**Ymir.**—The Ymir Mining Company has decided to spend \$100,000 in prospecting both the old and new Ymir leads. Several diamond drills are now at work and the force will be increased.

On the old vein it is the intention to push the drills some 500 or 600 feet below the present 1,000 foot level.

**Trail.**—During January the Trail smelter treated 6,452,624 lbs. of lead ore, which produced 2,979,631 lbs. of lead. The principal shippers were the St. Eugene with 2,752,952 lbs. ore producing 1,650,715 lbs lead; the Reco with 595,639 lbs. ore producing 237,292 lbs. lead; and the Blue Bell with 552,821 lbs. ore producing 351,885 lbs. lead.

**Hosmer.**—The tunnel on the Hosmer Coal Mines Company's property has now reached a depth of 4,150 feet from the entrance. To reach the limit of their grounds the company will have to drive their tunnel 7,980 feet, but it is thought all workable seams in the series will have been cut before that. There are 14 to 16 seams of coal and the tunnel is now approaching No. 9, so there are five seams still to be cut.

Ten more coke ovens are being built, making a total of 80 ovens in commission.

**Nelson.**—William Maher has bonded the Echo group at Sheep Creek to a party of Nelson, Rossland and Trail operators.

The decision of the United States Supreme Court that the duty on zinc ores imported into the United States is illegal

will likely make things hum in the Slocan. The court has ruled that duties paid on zinc ores must be refunded. The Whitewater, Ruth, Lucky Jim and other properties have been large shippers of zinc to the United States, and this decision means much to them. It is expected that the Lucky Jim, Blue Bell, Bosun, and Jackson will resume active operations in the immediate future.

A strike has been made in the Summit mine of a pay streak three feet wide, showing gold values of \$470 per ton. The Summit has been a small shipper for two years, but a good deal of development has been done.

**Kaslo.**—The Wagner mine has been bonded for a large sum to D. C. Corbin, in conjunction with the C. P. R.

The Maestro, at Ainsworth, is being steadily operated by H. Gregerich and Grant King. Some ore is being taken out and regular shipments are being maintained.

The old Payne mine at Sandon is to be thoroughly gone over and tested with diamond drills. A group of Montreal men are behind the project, and if the drilling shows satisfactory results

it will probably cause a revival of mining activity around Sandon.

Owing to the demoralized condition of the K. and S. railroad the February shipments were very small, but the output for March will probably be heavy.

The Flint mine is again on the shipping list.

**Nanaimo.**—The Nanaimo-Vancouver Coal Company has met with very encouraging results in the development of its property. Two large seams have been struck, the upper one four feet thick, and the lower one seven and a half feet. The company has also twelve feet of fire clay on the property. The property is at present under bond to eastern parties.

Some 4,000 acres of coal lands in the Cedar, Cranberry and Oyster districts, adjacent to Nanaimo, have been purchased by a big syndicate.

**Vancouver.**—The Ingenika-Findlay River Development Co. has acquired the copper claims held by the Moresby Island Developing Co., and a gang of men has been sent north to develop the properties.

## MINING NEWS OF THE WORLD.

### GREAT BRITAIN.

The export duty on diamonds from Damaraland will be altered to one-third ad valorem on sale prices, and not 1s 3d, as reported.

In order to encourage research work with radium a new institute is being formed to be called the Royal British Radium Institute. The council contains distinguished names, such as Sir William Ramsay, Sir Frederick Treves, and Prof. J. J. Thompson.

The principal source of radium is the mineral pitchblende, which is found principally in Bohemia and Cornwall.

The coal owners of Notts and Derbyshire are combining for the purpose of building a rescue station, which is to be erected close to the Sherwood Colliery, Mansfield. The Duke of Portland has given a site and the estimated cost of the building is £1,500.

### GERMANY.

An international syndicate in which Germany, France, and Great Britain are principally interested, has been formed for the exploration of the iron ore deposits in Morocco.

### CHINA.

A concession has been granted by the Chinese Government to work mines in Hainan, near Hong Kong. It has been known for some time that there are large deposits of gold, tin, coal and iron in Hainan, and it is said that the concession is a valuable one.

### AUSTRALASIA.

Owing to labour troubles and the unsatisfactory condition of the market the famous Broken Hill Mine, one of the largest producers of lead in the world, shut down for an indefinite time on March 15th.

The employees of the State of Western Australia are vigorously opposing proposed amendments to the Workers' Compen-

sation Act. The employers claim that it is really class legislation, and that the Government should not interfere with private enterprise. The proposed amendments, among other things, will make employers liable for accidents caused by wilful misconduct, and classes certain diseases peculiar to worker's callings, such as miners' complaint, etc., as accidents.

A new smelting process to treat refractory ores, to extract gold and silver from ore, containing besides the precious metals, also arsenic, zinc, galena, antimony, and traces of copper, has been put in operation at the Moruya Gold and Silver Syndicate's mine. The process is known as the Oxy-Hydro smelting process.

The dredging industry in New Zealand has been steadily decreasing. During 1908 several companies went into liquidation, and others did not pay expenses. The total gold yield has been on the down grade for several years.

### BELGIUM.

A plant for the electrical production of steel has just been put down at the works of the Cockerill Company at Seraing, Belgium.

### SOUTH AFRICA.

The difficulties caused recently by the flooding of the Witwatersrand mines are pretty well over. The flooding increased the amount of water dealt with by the Knights Deep mine from 1,000,000 gallons to 1,700,000 gallons in 24 hours. At the Knights mine 24 natives were imprisoned by the floods, but were rescued with great difficulty.

The number of Chinese labourers in the Rand mines decreased last year by 21,574.

A shipment of 6,000 tons of Transvaal coal has been sent to India. This is the first shipment of Transvaal coal ever sent there.

Rhodesia is a country of small mines. Analysis of a recent return shows that 33 per cent. of the gold output came from mills of five stamps or less; 52 per cent. from mines having

from 5 to 10 stamps, and only 15 per cent. from mines having more than 10 stamps each.

### UNITED STATES.

The Fink smelting plant at Garfield, Utah, has been started again and experiments are to be carried on for some time.

The Engineering and Mining Journal estimates the production of platinum in the United States during 1908 as 510 oz. The production during 1907 was 357 ounces.

The Pennsylvania Steel Company has announced a reduction in wages of approximately ten per cent. to take place April 1st.

Owing to recent heavy rains in California a large number of placer and quartz properties have been compelled to suspend

operations, but as soon as the surplus water has drained off work will be resumed.

### MEXICO.

The production of the Cananea Con. Copper Co. is averaging a trifle over 67 tons per day, and the output for February was 3,752,000 lbs., the highest since the resumption of operations. Various improvements are under way, but no effort will be made to push the yield beyond the 4,000,000 lb. mark until the demand for copper is firmer.

The International Oil and Gas Co. of Indianapolis, Ind., is soon to begin drilling for oil in the eastern part of Chihuahua. The company has oil rights over nearly 10,000,000 acres.

Legal difficulties with the people who furnish the wood used as fuel at a number of the mines in Taviche, Oaxaca, are making it difficult to obtain necessary fuel before the rainy season sets in.

## COMPANY NOTES.

### DOMINION COAL PAYS 1 PER CENT.

Directors of the Dominion Coal Company have declared the regularly quarterly dividend of 1 per cent. payable April 1st, to shareholders of record March 19th.

When the Privy Council judgment was announced there was a feeling that the Coal dividend might be postponed. The announcement now comes, therefore, as a surprise to many.

### ANOTHER BUFFALO DIVIDEND.

The Buffalo Mines Company has declared the regular quarterly dividend of 5 per cent., payable April 1st, and an extra dividend of 3 per cent., payable May 15th.

The previous dividend was of 5 per cent., and an extra of 1 per cent. each month for the quarter, payable January 2nd.

### COBALT CENTRAL CUTS DIVIDEND.

Cobalt Central has declared a quarterly dividend of 1 per cent., a reduction of 1 per cent., as compared with the preceding quarter. The dividend is payable May 15th, to stock of record of April 15th.

### CROWN RESERVE DIVIDEND.

The directors of the Crown Reserve Mining Co. have declared the regular quarterly dividend of 6 per cent., with a bonus of 9 per cent., making a total disbursement of 15 per cent. for the quarter ending March 31st, 1909. This is almost double the last payment, which was 16 per cent. for the six months ending December 31st, 1908.

It is said that after the quarterly disbursement there will be a surplus of \$50,000, which will be carried to the reserve fund, bringing that fund up to the total of \$397,000.

### TEMISKAMING MINING CO.

The annual meeting of the Temiskaming Mining Co., Ltd., was held in Toronto on February 20th.

The mine's production during its fiscal year amounted to 831,000 tons, which produced 1,026,285 ounces of silver, of a net value of \$494,211.46. The cost of production during the year has averaged 82.5 cents per ounce.

The quarterly production shows that it has been increasing gradually, as shown below:—

|                           | Ounces.      | Value.       |
|---------------------------|--------------|--------------|
| February to April.....    | 103,690.19   | \$45,193.15  |
| May to July .....         | 220,401.28   | 108,341.57   |
| August to October .....   | 314,287.82   | 150,288.63   |
| November to January ..... | 387,906.60   | 190,388.11   |
| Totals . . . . .          | 1,026,285.89 | \$494,211.46 |

At the present time there are 16,000 tons of ore on the Temiskaming dumps, having an estimated value of one-quarter million dollars. This ore is to be concentrated during the present year at an expenditure of probably \$100,000.

On January 31st the company had as cash in hand and cash value of ore in transit \$122,761.07. The next dividend will be paid on April 1st.

The small plant that has been used is now being kept as an auxiliary plant, and the new plant, with its greatly increased capacity, will enable the management not only to do much more extensive mining, but to develop the mine and block out ore.

No. 1 shaft has been continued to the 250 foot level, and the new No. 2 shaft is down below the 200 foot level, and is to be continued farther.

From shaft No. 1 there have been 1,648 feet of drifting, 519 feet of cross-cutting, 587 feet of sinking and raising.

At the 200 foot level 258 feet of drifting has been done and 469 feet of similar work at the 250 foot level.

The officers for the current year are: Burr E. Cartwright, President; R. T. Shillington, M.L.A., Vice-President; Alex. Fasken, Secretary-Treasurer; Richard A. Cartwright, of Brockport, Pa., and Joseph L. Wheeler, of Marion, S.C., are the other directors, and Norman R. Fisher, M.E., is the general manager and engineer in charge.

### CROW'S NEST PASS ANNUAL MEETING.

Several changes were made in the directorate of the Crow's Nest Pass Coal Co. at the annual meeting held recently in Toronto.

At the meeting President G. G. S. Lindsay, Vice-President Senator Jaffray, Third Managing Director Sir Henry M. Pellatt and Mr. E. R. Wood, all residents of Toronto, declined further to serve on the Board, though urged to do so.

The directors chosen were: Elias Rogers, Toronto; Col. Clough, New York; J. P. Graves, Spokane; W. F. Robertson, Granby, Que.; E. C. Whitney and H. B. McGiverin, M.P., Ottawa, and R. N. Young, Secretary of the company.

#### CITY OF COBALT DIVIDEND.

A 3 per cent. quarterly dividend, payable April 15th, has been declared by the directors of the City of Cobalt Mining Co. The dividend is 3 per cent. on the new capitalization of \$1,500,000, and is therefore equal to 9 per cent. on the old capitalization of \$500,000.

#### LE ROI NO. 2 COMPANY.

The eighth annual meeting of the Le Roi No. 2 Company was held in London, England, on February 26th.

The accounts show a balance in favor of profit and loss of £53,053 2s 6d, after writing off £19,795 2s 10d as depreciation on development, machinery, plant, buildings, etc. Out of this dividends of 6s per share, absorbing £37,800 have been paid, and the directors recommend that £10,000 be placed in the general reserve account.

The tonnage shipped amounted to 29,648 tons of an average value of \$23.60 per ton. Diamond drilling has confirmed the existence at a depth of about 1,200 feet, of what is undoubtedly the continuation of the south vein of the Le Roi mine.

In order to open up this ore body, it has been decided to continue the sinking of the main shaft from the 900 foot level. This will be greatly facilitated by the fact that the company have leased the Nickel Plate compressor, which will furnish the requisite amount of air.

The reports of the consulting engineers, Messrs. Hill and Stewart is substantially as follows: The total footage accomplished is 4,572.1 feet.

The greater portion of the development work has been done on the 300 foot level. Connection has been made with the California workings during the year, a distance of 309 feet, having been driven from the Josie 500 foot level for this purpose. This connection has improved the ventilation of both mines.

The work on the 700 foot level of the Josie has been directed towards opening up the Hamilton vein. The work has located the downward continuation of the East Hamilton shoot. This ore body is now being opened up from the 703 stope, but to make the work continuous a raise will have to be put up to connect with the 500 foot level on account of the ventilation.

The development during the year has been 3,902.1 feet of drifts, 400.5 feet of cross-cuts and 269.5 feet of raises and winzes, or a total of 4,572.1 feet, as compared with 2,793.1 feet last year. The development work has cost \$58,603.17 for driving and cross-cutting, and \$6,196.55 for raising, or \$14,172 per foot, as compared with \$14,576 last year.

During the year 3,606.5 feet were drilled in the Josie, and 3,833 feet in No. 1 mine, by the diamond drill. The work cost in labor and material \$2.39 per foot, as against \$2.61 per foot last year.

The most important discovery during the year with the diamond drill was the downward continuation of the south Le Roi vein, located at a depth of 1,200 feet close to the boundary of the Annie claim of the Le Roi Mining Co.

During the year five new stopes have been opened up on the Hamilton vein, and preparations are now being made to open up another in the east tramway tunnel. Three of these stopes are situated on the 300 foot level and two on the 700 foot level.

During the year 15,044.5 tons have been crushed, averaging .107 ounces gold, .137 ounces silver and 4.6 per cent. copper.

The tails from the above have been worth .032 ounces gold and .42 per cent. copper. The cost of milling this year has been \$1.14 per ton, as compared with \$1.37 last year, when 11,840 tons were milled.

The total amount of ore and waste raised from the mine was: Mixed ore, 40,034 tons, second-class and mill ore, 5,453 tons; actual waste, 12,215 tons. After hand-picking the output resolved into: Shipping ore, 29,648 tons; concentrating ore milled, 13,139 tons; concentrating ore placed on dump, 2,700; total of shipping ore and concentrating ore milled and placed on dump, 45,487 tons; waste, 12,215 tons.

The stoping costs amounted to \$175,765.68. The cost per dry ton of ore mined was \$3.60. There has been written off for depreciation \$83,145.61, averaging \$1.71 per ton. This makes the total cost of mining \$5.31 per ton. The gross value of the ore was \$699,740.77 or \$23.601 per ton. The values in the ore were: gold, \$19,194; silver, .379; copper, \$4.028.

The receipts from the smelter amounted to \$535,245.55, or \$18.053 per ton. The total smelting charges on the above, direct and indirect, have been \$5.548 per ton.

During the current year efforts will be chiefly devoted to the development of the property at depth, in order to open up and extract the ore now proved by the drill to enter the company's ground at a depth of 1,200 feet. The retimbering of the main shaft must also be undertaken in order to preserve it in the effective state necessary in view of the prolonged life of the mine which the successful development at great depth must naturally entail.

#### NICOLA VALLEY COAL AND COKE CO. REPORT.

The annual report of the Nicola Valley Coal and Coke Co. shows that the mines are being developed on a large scale, and that the market is growing rapidly.

The improvements to equipment at the mine above ground are as follows: Tipple house, trestle and chute at No. 4 mine; four cottages, powder magazine, fire hall and blacksmith shop, etc; extensions to waterworks system, and various works of minor importance.

The company have five workable seams, having a total thickness of 49 feet. Four of these seams are at present being worked. The Jewel seam (18 feet 6 inches thick) has been developed the most. The main tunnel has been driven nearly 1,300 feet, and is well timbered and laid with track for the whole length.

The following are the directors for the present year: John Hendry, President; Alex. McLaren, Vice-President; W. H. Armstrong, Managing Director and General Manager; J. J. Plommer, Secretary-Treasurer; R. P. McLennan, F. R. Stewart, Geo. E. Trorey, H. B. Wright, L. N. Mackechnie, M.D., Directors.

#### LA ROSE CONSOLIDATED MINES COMPANY.

Notice is hereby given that a dividend of 3 per cent. for the quarter ending 28th February, 1909, and a bonus of 1 per cent. has been declared upon the outstanding capital stock of the company, and will be paid on the 20th day of April, 1909, to shareholders of record at the close of business on 1st April, 1909.

By order of the Directors, the transfer books will be closed from the close of business on 1st April, 1909, and remain closed until 10 a.m. on 27th April, 1909.

Dated the 22nd day of March, 1909.

#### LA ROSE CONSOLIDATED MINES COMPANY.

Per D. A. DUNLAP,

Secretary-Treasurer.

# STATISTICS AND RETURNS.

## COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt camp, and those from January 1 1909, to date:—

|                            | Week ending<br>Mar. 6. | Since<br>Jan. 1. |
|----------------------------|------------------------|------------------|
|                            | Ore in lbs.            | Ore in lbs.      |
| Buffalo . . . . .          | 45,210                 | 178,220          |
| Coniagas . . . . .         | 62,500                 | 334,405          |
| Crown Reserve . . . . .    | 62,220                 | 967,920          |
| Chambers-Ferland . . . . . | 60,000                 | 202,000          |
| City of Cobalt . . . . .   | 75,000                 | 465,930          |
| La Rose . . . . .          | 195,000                | 2,462,340        |

| T. & H. B. . . . .         | 60,000                  | 504,060          |
| Muggley Con. . . . .       |                         | 72,900           |

Ore shipments to March 6, 1909, are 10,958,993 pounds, or 5,479 tons. The total shipments for week ending March 6 were 1,055,706 pounds, or 527 tons.

## CROW'S NEST PASS OUTPUT.

The output of the collieries of the Crow's Nest Pass Company for the week ending March 12th was 16,423 tons, a daily average of 2,737 tons.

The output for the week ending March 19th was 17,936 tons, a daily average of 2,989 tons.

## BRITISH COLUMBIA ORE SHIPMENTS.

The following are the ore shipments for the week ending March 5th and year to date:—

### Boundary Shipments.

|                       |        |         |
|-----------------------|--------|---------|
| Granby . . . . .      | 21,016 | 175,809 |
| Mother Lode . . . . . | 7,728  | 80,136  |
| Snowshoe . . . . .    | 4,142  | 32,838  |
| Other mines . . . . . | .....  | 2,094   |
| Total . . . . .       | 32,886 | 290,877 |

### Rossland Shipments.

|                                |       |        |
|--------------------------------|-------|--------|
| Le Roi . . . . .               | 2,479 | 7,849  |
| Centre Star . . . . .          | 3,485 | 21,953 |
| Le Roi No. 2 . . . . .         | 1,045 | 5,651  |
| Le Roi No. 2, milled . . . . . | 260   | 2,080  |
| Other mines . . . . .          | ..... | 5,462  |
| Total . . . . .                | 7,269 | 42,995 |

### Slocan-Kootenay Shipments.

|                 |       |        |
|-----------------|-------|--------|
| Total . . . . . | 2,990 | 30,149 |
|-----------------|-------|--------|

March 19.—Connellsville coke, f.o.b. ovens:—  
Furnace coke, prompt, \$1.50 to \$1.60.  
Foundry coke, prompt, \$2. to \$2.15.

**Metals.**

March 19.—Tin, Straits, 28.50 cents.

Copper, prime Lake, 12.75 cents.

Lake, arsenical brands, —

Electrolytic copper, 12.25 to 12.35 cents.

Copper wire, 14.25 cents.

Lead, 4.05 cents.

Spelter, 4.85 cents.

Sheet zinc, 7.25 cents.

Antimony, Cookson's, 7.90 cents.

Aluminium, 22 to 24 cents.

Nickel, 40 to 47 cents.

Platinum, \$22.50 to \$23.50 per ounce.

Bismuth, \$1.75 per lb.

Quicksilver, \$45 to \$46 per 75 lb. flask.

**"THIS IS  
THE ROOFING  
THAT NEEDS  
NO PAINTING"**

**T**HERE was a time when everybody bought roofing that required painting. It was the regular thing to do. In fact there was nothing else to do, for all roofings were "smooth surfaced" and required painting regularly to keep them from deteriorating.

Now there is *Amatite*, an improvement over painted roofing, having a *real mineral surface* imbedded in pitch—making a kind of flexible concrete.

*This mineral surface needs no painting.* The waterproofing material, Coal Tar Pitch, is the greatest enemy to water known. It is the base of many waterproof paints. Only in a paint the pitch is diluted and made into a thin film, whereas the *Amatite* waterproofing is *solid pure Pitch*—two layers of it. It would take something like a dozen coats of pitch paint to equal in thickness that upper sheet of pitch in which the *Amatite* mineral surface is buried. And under that heavy sheet of pitch is a layer of wool felt and under that another sheet of pitch, just as thick as the

outer one. And below them all is another layer of strong felt. That makes two roofs in one.

If the storms wore away the mineral surface and dug through the pitch and destroyed the felt they would still be only half way through. And if the weather then removed the next sheet of pitch, you would still have left a final layer of felt—nothing more or less than an ordinary smooth surfaced roofing which could keep off the rain very nicely if painted every year or two.

But as a matter of fact, the weather never gets past that mineral surface securely gripped in its matrix of pitch.

*The mineral surface is there to stay.* No painting—no bother—no further expenses after the roof is once laid.

We should be glad to send you a free sample of *Amatite*, and you can see for yourself how much better it is than the smooth surfaced kinds. Address our nearest office.

When answering Advertisements please mention THE CANADIAN MINING JOURNAL.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

# Geological Survey

**PUBLICATIONS** The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects

## MARITIME PROVINCES

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

## QUEBEC

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the province north of the St. Lawrence are also available.

## ONTARIO

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

## THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

## BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

## YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

## THE NORTH-WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of reports and maps are sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

*Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.*

### THE FOLLOWING REPORTS AND MAPS HAVE BEEN ISSUED DURING THE PAST YEAR

- |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# Ontario's Mining Lands

---

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite ; copper in sulphide and native form ; gold, mostly in free milling quartz ; silver, native and in other forms ; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,  
**Toronto, Canada.**

# PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

## Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement.

The price of prospecting licenses is \$5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only \$2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, \$10.00 per acre, and on lands situate less than 20 miles from such a railway, \$20.00 per acre.

Superficial products and building materials are sold \$2 and \$4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed

lands; work must be bona fide begun within two years and \$500.00 spent each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose its products, are granted on payment of a fee of \$10.00 and a rent of \$1.00 acre per annum. Such licenses are valid for one year and are renewable payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by poles.

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with Mr. MILTON HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlet copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

**The Hon. Minister of Colonization, Mines and Fisheries**  
Parliament Buildings, Quebec.

## Province of Nova Scotia

CLYDE PATENT WIRE ROPE WORKS  
Rutherglen, Glasgow, Scotland

## WIRE ROPES

For Winding and Haulage in Collieries and Mines, Aerial Ropeways, Transmission of Power, Suspension Bridges, etc. **SPECIALLY FLEXIBLE ROPES** for Hoists, Winches, Loading and Discharging Cranes, Shipping Purposes, Towing, Alligator and Dredger Ropes, etc. **SPECIAL ROPE FOR LOGGING.**

Our Ropes are made from wire drawn for our exclusive use, and are at work all over Canada. Messrs. Nova Scotia Steel & Coal Co., Ltd., who use them largely, write that one of our haulage ropes at their Wabana Mine has been in use for **5 years**, drawing over 1,750,000 tons and still in good condition. From the Atlantic to the Pacific they are well known and our agents will be only too pleased to give all information to enquirers. They may be had from the following, viz :

**Nova Scotia : Wm. Stairs, Son & Morrow, Limited.**      **New Brunswick : W. H. Thorne & Co., Limited.**  
**Montreal and Toronto : Drummond, McCall & Co.**      **Vancouver, B.C. : John Burns.**      **Winnipeg : David Philip, Portage Ave.**

**HIGHEST Quality. MODERATE Price. Prompt Delivery. SATISFACTION in use.**  
Cables : "Ropery, Rutherglen."      Codes : A. B. C. (4th and 5th Editions), A.I., Liebers and Private.

## INSOLVENT NOTICE

UNDER THE WINDING UP ACT OF CANADA  
IN THE MATTER OF

### The Asbestos Mining & Manufacturing Company IN LIQUIDATION

Tenders will be received by the undersigned at the office of John J. Griffith, 125 Wellington Street, Sherbrooke, Que., up to noon on

**Thursday, April 15th 1909**

for the purchase of the Mines, Mining Rights, Buildings and Immoveable Property, Plant and Machinery of the Asbestos Mining & Manufacturing Co.

The said immoveable property being the north-east half of the lot No. 25 in the Fourth Range of the Township of Wolfestown, in the County of Wolfe, in the Province of Quebec, and which is now known and described upon the official cadastral plan and book of reference of the said Township of Wolfestown, as the Lots numbers 25C and 25D in the said Fourth Range, together with all the buildings, plant and machinery in and upon the said property, save and except certain machinery, the property of the Canadian Westinghouse Company, Limited, and certain machinery the property of the Jenckes Machine Company, Limited, now being upon the said property, and which machinery so excluded the said Companies shall have a reasonable delay to remove in case of sale.

The highest or any tender not necessarily accepted.

Particulars in regard to the said property will be furnished on application to the Joint Liquidator at the office of John J. Griffith, Sherbrooke.

**JOHN J. GRIFFITH & F. W. TOFIELD,**  
Office of Joint Liquidator

**JOHN J. GRIFFITH,**  
Accountant Auctioneer, Sherbrooke.

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Mineral or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579,037 the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
 Silver Medal—Coal and Coke—Paris Universal Exposition, 1903.

Coke Ovens and Coke Ovens at Fernie, Coal Creek, Michel and Bonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 50,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, **WE ARE GIVING SATISFACTION.**

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the West.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke uses, and what coke gives him best satisfaction.

**Our Analyses Speak for Themselves.**

# DOMINION

# OF CANADA

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

**W. W. CORY, Deputy of the Minister of the Interior**

## The "Little Hardy" Coal Cutter

Holes at Floor Level or Roof Level or in any intermediate position in Coal or Dirt Band, &c.

Equally suitable for Holing and Shearing.

The Lightest Coal Cutter in the Market.

Nearly 700 Machines at work. 93 in use by one Canadian Company.

## The Hardy Simplex Hammer Drill

Weight 22 lbs. Bores 6 ft. Deep.

Automatically Rotates the Drill [Steel and lows out the Cuttings  
FOR SINKING, &c.

**SOLE MAKERS**

**The Hardy Patent Pick Co., Limited**  
SHEFFIELD, ENGLAND

Stocks of these machines kept by Messrs. A. C. Thompson  
Co., Limited, North Sydney, Nova Scotia, Canada.

## WHY NOT TRY A "CLEVELAND" STOPE DRILL

### OUR PROPOSITION.

We will gladly ship you a complete equipment for trial, and guarantee that it will do more work than any similar machine on the market at less cost for maintenance.

Our aim has been to make an efficient, "fool proof" simple and durable machine, and we ask that you give us a chance to prove that we have succeeded.

**Try One with your other Drills and see the difference.**

Canadian Office and Works,

MONTREAL

## SULLIVAN CLASS "WC" AIR COMPRESSORS

require smaller boiler capacity, i.e., burn less coal than any slide-valve compressor of like size: full Corliss valve gear on both high and low pressure steam cylinders make these machines the equal in fuel economy, of the best class of Corliss compound compressors.

The air is compressed in two stages, with a large intercooling area.

"WC" compressors cost less to build, transport and house than cross compound machines, on account of their tandem construction. Bulletin 658A.

Rock Drills, Hammer Drills, Diamond Drills, Coal Cutters, Hoists.

## NORTH AMERICAN CONSERVATION CONFERENCE.

It is no exaggeration to affirm that the North American Conservation Conference is the official beginning of a movement that will affect profoundly the future history of Canada and this continent generally.

Sessional Paper, No. 90, issued by the Dominion Parliament, embodies a Declaration of Principles as drawn up by the Conference. The opening paragraph runs thus: "We recognize the mutual interests of the nations which occupy the Continent of North America and the dependence of the welfare of each upon its national resources. We agree that the conservation of these resources is indispensable for the continued prosperity of each nation." Then, as summing up the spirit of the Conference, we find this:—"We agree that those resources which are necessities of life should be regarded as public utilities, that their ownership entails specific duties to the public, and that as far as possible effective measures should be adopted to guard against monopoly."

The paper then proceeds to define its attitude towards public health, forests, waters, lands, minerals, and protection of game.

We have especial concern with the section on minerals. It is proper, considering the importance of the matter, to quote the full text of this section:—

### Minerals.

"We recognize the mineral resources as forming the chief basis of industrial progress, and regard their use and conservation as essential to the public welfare. The mineral fuels play an indispensable part in our modern civilization. We favour action on the part of each government looking towards reduction of the enormous waste in the exploitation of such fuels, and we direct attention to the necessity for an inventory thereof. Such fuels should hereafter be disposed of by lease under such restrictions of regulations as will prevent waste and monopolistic or speculative holding, and supply the public at reasonable prices.

"We believe that the surface rights and underground mineral rights in lands should be separately dealt with so as to permit the surface of the land to be utilized to the fullest extent, while preserving government control over the minerals.

"Regulations should be adopted looking to the most economical production of coal and other mineral fuels and the prolongation of the supply to the utmost. We favour also the substitution of water power for steam or other power produced by the consumption of fuel.

"Great economy in the use of fuel has resulted in the past from the application of scientific invention and the use of improvements in machinery, and further progress can be made in the same direction. We, therefore, recommend that all possible encouragement and assistance be given in the development and perfecting of means whereby waste in the consumption of fuel can be reduced.

"The loss of human life through preventable mining accidents in North America is excessive. Much needless suffering and bereavement result therefrom. Accompanying this loss there is great destruction of valuable mineral property and enhancement of the cost of production. The best method of eliminating these known and admitted evils lies in the enactment and strict enforcement of regulations which will provide the greatest possible security for mine workers and mines. We, therefore, favour the scientific investigation of the whole subject of mine accidents by the governments participating in this conference, the interchange of information and experience, and the enactment and enforcement of the best regulations that can be devised.

"Mineral fertilizers should not be monopolized by private interests, but should be so controlled by public authority as to prevent waste and to promote their production in such quantity and at such price as to make them readily available for use."

These declarations deserve careful attention. The Conference was called by the President of the United States. Delegates were present from Mexico, Canada, Newfoundland, and the United States. Their deliberations were conducted with one object in view. That object was to give strong impetus to the movement for the better conservation of our natural resources, and to excite international interest in that movement. In this, we believe, the effort will be successful.

To Canadian mining men the second paragraph quoted above will be instructive. Coming from a dignified continental committee, it carries large weight. Significant also is the reference to loss of human life through preventable mining accidents.

All thinking men will concur in hoping that the good work begun by the Conservation Conference will be continued.

### QUEBEC MINING LAW AMENDMENTS.

Quebec has moved slowly in the direction of better mining laws. For long there have been complaints from prospectors. Not alone is the present law unsuited to furthering the opening up of new mining districts, but in some cases it has actually deterred capital from entering the Province. Indeed the present law has a bad name, whether justly or unjustly is not for us to say.

The Quebec Department of Mines has not been

oblivious to this fact. Mr. Obalski, the technical head of the Department, has followed keenly for many years the trend of mining legislation in other countries. He has taken a prominent part in the discussions of the Canadian Mining Institute. The Hon. Mr. Devlin, the titular head of the Department, has made himself familiar with the needs of his Province. No doubt both of these gentlemen have had ample opportunity of learning the opinions of investors and prospectors regarding the present mining act.

Recognizing, however, that hasty and ill-considered changes are worse than any number of defects, the Quebec authorities have deliberated long. The bill now introduced by the Hon. Mr. Devlin will bring sweeping changes. It alters radically the conditions governing prospecting and acquisition of mining claims. The old prospecting license is to be done away with. It is to be replaced by miners' certificates, which will be issued by the Government on payment of a fee of ten dollars. Holders of certificates will be permitted to prospect all over the Province where the mining right belongs to the Crown, and where no previous right exist.

Further, following the Ontario Act, the prospector will be required to stake his claim in accordance with specific regulations, including a marked discovery post.

The changes outlined will become effective at the moment the bill is sanctioned. Holders of license under the present Act will not, however, be interfered with until January 1, 1910. After that date the amendments will apply to all alike.

So far as we are able to judge from the scanty information received, the Devlin bill is sound. The changes will make less thorny the path of the prospector, and we venture to predict that this summer will see more than usual activity in Quebec.

One crucial question, a question that the Quebec Department of Mines should approach with all possible care, is that of "discovery." We do not wish to refer harshly to that feature of the Ontario Act. But it is not improbable that Quebec may learn what to avoid in this particular respect by studying the operation of "discovery" requirements in her sister Province. Undoubtedly, on the other hand, Quebec can and will draw many good lessons from her western neighbor. We would also draw attention to the fact that British Columbia has an Act that works smoothly and well. Perhaps the highest praise that can be accorded that Act is the statement that there is little or no evidence of dissatisfaction. And, after all, what is needed is a minimum of legislation and a maximum of mining. An Act that covers scores of closely printed pages, an Act whose every clause is qualified and modified by endless riders, defeats its own end. Mining legislation, it is, or should be, designed to facilitate, not to impede the progress of an industry that is becoming more and more essential to the nation.

### ÆNEAS McCHARLES.

Æneas McCharles, the founder of the McCharles Prize, was born in Nova Scotia, where he received his education, and for some time taught in the public schools of the Province. He went out West sometime in the eighties and made money in Winnipeg by investing in real estate. He drew out with something to the good when the great boom burst, and settled in Sudbury, if the life of a prospector can be called settled. He joined a group of pioneers responsible for the exploration of the nickel range—hardy men, those pioneers, whose task is to march first and trace paths for the progress of the race.

His keen sarcasm, ready wit, and strength in debate made him a leader in much of the warfare against mining laws and other obnoxious legislation that used to trouble the prospectors of the north. But his familiar friends knew the warmth of his heart, and were always glad to smoke a pipe with him in the modest little building where he lived his lonely life. He was an indefatigable prospector, and had the rather unusual habit (among prospectors) of carving his name frequently on the trees. For many years he failed to make any money and lived on his dividends from Winnipeg. But his good fortune came at last. He sold the North Star mine to the Mond Nickel Co. for a sum that made him comparatively wealthy. But he did not change his manner of life in the least. His friends thought the loneliness and asceticism were not good for him. They were glad when he forsook his frying-pan and came to dine with them at the Balmoral.

The foundation of the McCharles Prize to encourage research, and the terms of his will in this connection reveal the essential largeness of his nature. The memory of Æneas McCharles will be kept green.

### A SOUTH AFRICAN DIVIDEND.

The Jubilee Gold Company, Limited, was organized in Natal in 1886. For three claims on the farm Turffontein, Witwatersrand, the company paid £9,000 in shares. Later it acquired more territory. Its authorized capital is £50,000 in shares of £1 each. All the shares are fully paid. It operates a 50-stamp battery, cyanide and slimes works, and other accessory plant. During 1908 the company reports 62,046 tons of ore crushed, yielding £86,781. Ore reserves, which are carefully developed, are reported at 178,567 tons.

Since the first year of operation, with the exception of the period occupied by the Boer War, the Jubilee has had a remarkable record in dividend paying. In no year has it distributed less than 25 per cent. in dividends. In 1894 the company declared distributions of 150 per cent. From 1903 onward the fortunate shareholders have received 50 per cent. dividends.

It is worthy of note that these enormous dividends have been made possible mainly by maintenance of ore reserves, along with careful elaboration of suitable

metallurgical processes. The company's aim has been to maintain reserve developed ore, amounting to about three times the tonnage crushed annually. The property is now estimated to have four years more to run.

### CANADIAN BANKING.

A fearless and decent newspaper or magazine is an incalculable blessing to any community. Collier's Weekly, Canadian edition, brought out recently an article on Canadian banking. The writer, Mr. Peter Ryan, speaks as one having knowledge. He makes a strong case against the branch system. He claims, and in this we concur with him most heartily, that the innumerable branch banks with which the Dominion is dotted, act merely as suckers by means of which the nation's savings are collected and transmitted to the large financial centres. He shows cause why the

### THE WORLD AND THE LIMIT.

Of all the influences that have told against the healthy development of Cobalt, Lorrain, Montreal River, Larder Lake, and Gowganda, the Toronto World has been the most pernicious. So indifferent has its management been to the consequences of wholesale wild-catting that it is now looked upon as the prime and proper channel through which mining fakirs must make their strongest appeal to the credulous.

We had thought that the Law tragedy, the Spears, Big Ben, Silver Mountain, and Aguanico incidents would have caused the World to cover its diminished head. But worse remained.

The Toronto World is not content with selling advertising space. Casuistry may justify the absence of censorship as regards its advertisements. No ingenuity can remove the stain of certain editorial lapses. Witness the following. On March 30 there appeared in the World a leaded reading notice, covering a double column space for the full length of the page. This notice was intended to be taken as an open declaration of the World's belief in Julian Hawthorne and all his works, including his Temagami-Cobalt areas—we had almost called them mining areas. In unmistakable language, as will be seen by referring to the accompanying cut, the World lent the seal of its approval to the most fantastic imposter that has yet inflicted himself upon Canada.

Julian Hawthorne, unworthy son of worthy Nathaniel, is a magazine writer. He is also a sublimated ass. Moreover, he has been shown up by one or two responsible mining journals in the United States. In fact he is so patently a pretender that we do not wish to waste more space upon him. Even to the oblique vision of the World the man must have appeared in his true colors.

Hence we must conclude that the Toronto World has accomplished the impossible—it has descended.

### Montreal River District on a Large Scale

RY

Tem-

Hawthorne Syndicate owns the Temagami-Cobalt Mines, Limited, The Elk Lake-Cobalt Mines, Limited, and The Montreal-James Mines, Limited, and is now branching out into the Shining Tree Lake and Welcome Lake districts.

It has, for some time past, been known to The World, and possibly also to the better-informed portion of the Toronto public, that Mr. Julian Hawthorne has been writing to friends of his in the States, inviting them to join him in a mining project in Ontario. Not until to-day, however, has full and trustworthy information on the subject been received.

This is due to the fact that, for reasons best known to themselves, Mr. Hawthorne and his associates have been conducting their operations very quietly; at any rate, they have thus far avoided publicity. So no mention of their proceedings has been made, and it was, indeed, by the merest accident that The World became possessed of the information.

#### THE TEMAGAMI-COBALT MINES PROPERTY.

The fact is, that the Hawthorne Syndicate has entered Ontario on a scale which might be described as stupendous. It is stated that the Syndicate, some time last September, started operations on what is known as the Diabase Peninsula, a white Diabase rock, within two miles of the Temagami railway, a piece of the road which has been uncovered since the line was

seen, the Welcome Lake district, but an area equally large. It is reported that they have recorded more than 100 claims (4000 acres) in that district alone.

#### BRAINS, PUSH AND MONEY.

From these data it would seem that the Hawthorne Syndicate is backed, not only by pluck, energy and foresight, but by no end of money as well. For operations on a scale such as theirs require big money, and when it is realized that the money they are spending is their own, and that they are not organizing stock companies, it will be understood that it means, on their part, deep-rooted confidence in the future of the Ontario silver zone. For mining of this sort. The World is free to say that it entertains high respect. We deem it more than probable that American pluck and push are going to win out once more. The members of the Hawthorne Syndicate are people of the kind that makes history; and we should not be surprised if, in this instance, they made money, too.

Supplies have been forwarded for two camps of one hundred men—one camp at Shining Tree Lake, the other at Welcome Lake. As soon as the snow melts, the Hawthorne Syndicate will begin systematic prospecting of their immense holdings. It is certainly remarkable that, until now, nothing has been known of the operations of these men. If nothing else had drawn attention to them, it would be thought that the amount of machinery and supplies going into their properties would have done so. However, The World at last presents the facts.

GO  
J. C.  
merc

C

United States system of banking is better in principle than our own—better, that is, for the people. Nothing could be more delightful for the bankers than the Canadian system.

All of which has a direct bearing upon the mining industry. It is time that we heard less of Mexican and West Indian ventures begun and continued by Canadian financiers backed by Canadian banks. It is time that we heard more of Canadian coal-mines, iron-mines, and all varieties of mines receiving business-like support from our own banks. Perennial platitudes from the pens of bank presidents are about as satisfying as the east wind.

### "GEOLOGICAL HIEROPHANTS."

Our volatile contemporary, Mining and Scientific Press, whose editorial pages are a well-spring of delight, took umbrage at certain geological polysyllables used by Messrs. Ransome and Calkins. As ill-luck would have it, these honest geologists injudiciously herded a lot of obfuscating longinquitous verbiage into one paragraph. This was too much for our occidental coeval. In wrath it let fly at those geologists and called them the bad name that we have printed above.

Apparently the shot told, for, after many days, Mr. Ransome sent a pungent and impassioned reply from Washington, D.C., begging the editor for heaven's sake to quit his joking. Which the editor promptly did. In the interim a goodly lot of sprightly letters had appeared in the Press.

The net results of the incident appear to be that two geologists are sore, and all things else are in statu quo.

### APLITE.

We publish on another page an interesting note from Mr. N. L. Bowen, of the Kingston School of Mining. Mr. Bowen has determined definitively the mineralogical composition of the aplites of Northern Ontario. Hence future discussion will have a clearer basis on which to begin.

It will be remembered by readers of Dr. W. G. Miller's Report on Cobalt (3rd Edition, page 65) that he alludes to the similarity in composition between the aplites of the Montreal River District and the granite dike on the University property. Mr. Bowen confirms this specifically, and adduces the necessary analytical facts.

### EDITORIAL NOTES.

Le Roi mine, it is announced, has been closed temporarily. This implies also that the Northport smelter will be put out of commission. The Le Roi Company apparently is considering the acquisition of new properties wherewith to strengthen its ore reserves. There is every reason to believe that the suspension of work will last for but a short period.

Canada is not to have a Royal Commission on Mining. Instead of this the less costly expedient of a standing committee of the House of Commons has been resorted to. It remains with the mining fraternity to keep this committee busy.

### GOWGANDA NOTES.

The roads into Gowganda are still passable, but they will soon break up in the April sun. The lakes become impassable first, for even in the coldest weather there is a lot of water and slush under the snow.

Four boilers consigned to the Reeves-Dobie and the Boyd-Gordon Mines, are on the road from Sellwood. Considerable difficulty is being experienced in getting them in. They weigh about four tons apiece. It is doubtful if they will reach Gowganda before the roads break up.

The Bartlett Mines, Ltd., have their machinery on the ground and are at present installing it.

The O'Brien Mining Co. have their machinery in place and have erected some of the finest buildings in the camp.

There are about 500 teams on the road between Charlton and Gowganda, and about 200 on the Sellwood-Gowganda road. Teams are in such demand that the railroads (T. & N. O. Ry. and C. N. O. Ry.) are trans-

Scene at Stopping-place half way between Charlton and Elk Lake.

porting teams and sleighs free of charge to Charlton and Sellwood.

The great question in the minds of the prospectors and investors in the Gowganda field is: When is the Government going to build a waggon-road into the camp? A good summer road is an absolute necessity, as without it the development of the camp will be greatly retarded, and the public will lose interest in it when results are not forthcoming.

People remember the immense sums spent by the Dominion Government in making the Caribou and Klondike goldfields accessible. The Ontario Government should make some return for the large revenue they have derived from the Silver Country, and the best investment would be in a good road.

Blind pigs are flourishing in Gowganda. The latest census showed fifteen. A magistrate and one or two policemen are very much needed to keep down the liquor traffic and other forms of lawlessness which are developing rapidly in the absence of legal restraint.

Three assayers have opened offices, but are not doing very much business. The average prospector declares he has silver on his claim and does not want any assay to destroy his dreams of affluence.

JAS. D. CUMMING.

## A BRITISH VIEW OF WESTERN CANADA.

Part of John Ashworth's Report, read before the Manchester Geological Society.

Some miles to the west or south-west of Winnipeg we passed the lignite coal fields of Souris, but it was not on our programme to visit them, and it was not until we reached Medicine Hat in the afternoon of the 13th September that we came into close touch with the Prairie lignite coal field. Our call here had reference principally to the bore-holes put down for natural gas at a depth of 1,060 feet.

The following is a short description of the strata passed through:—

The first 600 feet of the boring, 10 in. in diameter was through water bearing strata and ended in a sandstone formation lying between blue shales. The diameter of the bore at the bottom is  $4\frac{3}{8}$  inches. The blue shales readily disintegrate when exposed to water and air. The pressure of the gas is about 556 lbs. per sq. inch, and the yield about a million and a half cubic feet per 24 hours. Although this supply has been drawn on for twenty-four years, it has not yet shown any reduction in the yield. The gas is used for all sorts of purposes, the price for domestic supply being  $13\frac{1}{2}$  cents per 1,000 cubic feet, and for business purposes 5 cents per 1,000 cubic feet at a pressure of 8 ounces per sq. inch. The Railway Reservoirs are charged up to a pressure of 175 lbs. per square inch. This gas is used very extensively by the C. P. Ry. Co. in their shops for all sorts of heating purposes, and has effected a saving of at least \$60,000 per annum on an outlay for boring of only about 4,500 dollars.

After leaving Medicine Hat we called at Dunmore Junction to inspect another gas well recently bored by the C. P. Ry. Co. The well is 1,075 feet deep and has a diameter of ten inches all the way down. The pressure is 580 lbs. per sq. inch and on the opening of the stop valve for our edification the noise was deafening while the gas was blowing off and rose to a height of 200 feet.

Our next scene of investigation should have been Lethbridge, which place was reached at seven o'clock in the evening, but the delay at Schrieber compelled the directors of our movements to leave the Galt collieries unvisited much to the disappointment of every member of the party.

Near Lundbrek, on the 14th September, we saw the first lignite and Bituminous colliery in the district, which is noted for its freedom from snow during the winter, and is, therefore, most suitable for cattle ranching.

After leaving this district we commenced the ascent into the Rocky Mountains and at Frank we were aroused at 5.30 in the morning to view what was probably the greatest landslide of the world. This has been fully described in the transactions of the associated societies, but no one can possibly realize the enormous power which was brought into action in a moment without personally visiting the site.

The coal seams at Frank are perpendicular and are still being worked in the same manner as before the great landslide took place.

Having skipped the extensive collieries to the north of Frank, which are not in sight from the railway, our next call was at Coleman to see the extensive developments at that point. Mr. O. E. S. Whitesides, the General Manager, had made elaborate preparations for the entertainment of his visitors, but these had to be curtailed into a run into the mine for about  $1\frac{1}{4}$  miles

on cars drawn by an electric locomotive. The return journey was made at express speed, at a speed, in fact such as no engineer in the party had previously experienced in a coal mine.

At Coleman miners use the Wolf Lamp with internal self-ignition, and Negro powder is used for blasting. The dip of the mines is about 30 degrees. No. 2 seam is a steam coal and 14 feet thick. No. 4 is a coking coal and 7 feet thick. No. 5 is a steam coal 14 feet thick. The roofs and floors are rock; the holing or mining is all done by hand. The extraction is by pillar and stall, the pillars being 60 ft. by 60 ft and the rooms 15 ft. wide; 200 ft. on the higher side of the road is left in as a support for the roadway. The output is about 2,000 tons per day and an Ottumwa box car loader is in use. The mine ventilation is maintained by two Capell fans. The coke ovens are of the beehive type.

As is the case with the Crow's Nest Coalfield, the mines at Coleman are in the Cretaceous measures. The seams of coal are not continuous, however, and there is a complete break in the section between Coleman and Michel, yet they doubtless belong to the same coalfield.

When at Coleman the Crow's Nest mountain may be seen to the north, remarkable from the fact that this huge mass of limestone rock is out of its geological position.

At our next point of call a very hurried opportunity was given to view the surface arrangements of the Hosmer Mines. Here are thirteen seams of coal varying from 4 to 30 feet thick and these are being recovered by a tunnel driven at right angles to the dip of the measures and starting in about 600 ft. above the railway track. There are two parallel tunnels, the larger one being in three sections or compartments, two of which are for haulage, and the third one a travelling road and a pipe way. The other tunnel is for the return air. The tunnels have been driven in 3,400 ft. and have crosscut seven seams. The dip of the seams varies from 65 to 35 degrees. The first 847 feet of the tunnels is driven through the Fernie shales which form the basis of the coalfield.

The ventilation of the mine is effected by a Walker Fan 20 ft. by 9 ft. and can be used either as an exhaustor or as a blowing fan. The haulage is effected by compressed air locomotives. Wash house, baths and lockers are provided for the miners. The mine cars are constructed to hold 2 tons each. Two hundred and forty coke ovens are calculated to give an output of 300 tons of coke per day. During the forest fire, which destroyed Fernie, these coke ovens were made use of by the fugitives and many lives were saved.

Under the terms of their purchase these mines could not commence to ship coal until after the 1st December, 1908.

Our next stop was at the fire devastated town of Fernie. Of the old landmarks only the offices of the Crow's Nest Pass Co., Ltd., remain and a few houses at the western end. This is the third time that Fernie has been partially destroyed by fire. The Coal Creek Mines of the company are situated up the creek of that name about five miles from the town, and during the afternoon a number of our party visited the mines and went underground, whilst the majority contented themselves by viewing the surface arrangements.

Practically all the mines belonging to this Company are in British Columbia, and have an acreage of 250,000.

They are opened and in course of development at three points, viz.: Michel, Coal Creek, and Carbonado, or Morrissey. The measures dip mainly to the eastward at an angle of about 30 degrees, and further to the east become flat.

The capital of the company is \$10,000,000, and the output of the mines is equal to more than a million tons per annum. The coal is highly bituminous, the small coal being made into coke and supplied to the smelters both in Canada and in the States. It has 1,128 coke ovens equal to an output of 2,000 tons per day, and finds employment for 2,470 men.

Wolf safety lamps are used in all the Company's mines and as a souvenir of this visit one of these lamps was presented to each visitor by the First President of the Crow's Nest Pass Coal Co., Ltd., G. G. S. Lindsay, Esq., K.C.

The attention of some of the visitors was called to a serious accident of a somewhat unusual character which had occurred in No 2 mine at Coal Creek, and doubtless this was the reason why some of the party were anxious to make an underground inspection.

This mine has been developed principally on the pillar and stall system of extraction, but the pillars are very irregular in size and some little longwall has been tried. The mine, though it has a general dip towards the east, is by no means on a level bed, there being a syncline and also an anticline, and it was on top of the anticline that "bumps" developed. Some of these bumps caused fatal accidents and engendered a scare amongst the miners. During the summer of last year the most serious bump occurred in the main haulage way and closed in the road, shutting off 24 men who were in that portion of the mine. After very strenuous efforts on the part of the management 22 out of the 24 were rescued alive about two days afterwards. This bump affected the floor principally, and as being of a soft nature, it was squeezed up to the roof and a considerable volume of fire damp was given off. The general opinion was that the pillars were too small and hence that there was too little support for the superincumbent weight of the mountain above, which at this point would give a cover of about 3,000 feet. The management have been practically compelled to abandon the developed workings on the pillar and stall system, and to open out new districts on what is termed "retreating longwall," that is to say, the mine is to be divided into districts with separate panels, each panel being 900 by 900 feet, and the pillars between the panels are to be 100 feet wide and the pillars left to support the levels and haulage road are to be not less than 300 feet thick.

The different modes of working the coal seams of this coalfield might evoke a very interesting discussion, because the coals are of a very soft nature, and the mines are gaseous and in some cases as the one reported to this Society by my brother, Mr. James Ashworth (Notes on the Crow's Nest Coalfield, 1905; also Inst. of M. E.'s volume xxix., and on outburst of Gas and Coal at Morrissey), the coals are subject to huge outbursts of fire damp and fine coal dust. Although the mines are worked from adit levels, yet the mountains rise so quickly that most part of the seams at Coal Creek may be taken to have a cover of 3,000 feet. The roof in all cases is hard and the gas appears to lay in the floor strata principally. There cannot be a doubt but that the miners here favour the pillar and stall method of working.

Time did not permit of very close investigations of

the possibilities of this coalfield, and we were early next morning en route for Moyie to visit the largest silver lead mine in Canada. The crude ore of the St. Eugene Mine contains about 18% of lead, but the ore is concentrated before shipment, and as sent to the smelter contains about 65% of lead and 32 ounces of silver to the ton. The output last year (1907) was 607,000 ozs. of silver, and 27,000,000 lbs. of lead. There are two principal parallel veins, and the bottom level is the 1,900-foot level or 4,000 feet from the top of the mountain. The ore of this mine would be more valuable if it were not for its zinc content.

Shortly after leaving Moyie, one of our geologists who knows the district assured us that there was plenty of alluvial gold amongst the gravel of the river bed, but it would require heavy machinery to deal with it on account of the size of the boulders.

Our stay at the city of Nelson was too short to visit the mines or the Electrical Zinc Smelter, but we called at the Bonnington Falls to visit the West Kootenay Power and Light Co.'s plant. There is no trouble here regarding the destruction of the scenic beauties of the falls, and the electricity produced is carried off at a high tension right away to Rossland. The power applied is 4 units of 8,000 h.p. each.

Our next call was at the Rossland Power Smelter. Some 10 to 15 tons of lead piping is made here every day, the workmen being mostly Italians. The Trail Smelter is the oldest copper reduction works in the Kootenay, having been erected in 1894. The lead product from the furnaces is refined electrolytically.

The electric current from the Bonnington Falls is received here at a pressure of 20,000 volts. The horse power of the motor in use is 3,000.

From Trail to Rossland, where we paid our next visit, the rail track rises 2,000 feet in 13 miles. At the noted Le Roi Mine we went down to inspect the 1,650 foot level and stopes. The shaft is an inclined one and the cage is fitted with a safety catch arrangement to arrest its fall in case of the rope breaking. We also visited the Le Roi No. 2 or Josie Mine, and descended to the 500-foot level. Here we saw a diamond drill at work boring down to the 700-foot level. Following this visit we also descended the Centre Star to the 1,650 level, the mine having a total depth of 2,300 feet. The haulage machinery is strong enough to haul from 3,000 feet, and the engine draws at the rate of 1,000 feet per minute.

The day we spent at Rossland was one of the most strenuous of the whole trip, and, in fact, did not end until early the next day, when our entertainers saw all aboard for Trail, at which place we went to bed in our own sleepers and the train journeyed on to Greenwood, where we arrived on September 17th, to inspect the Mother Lode Mine, belonging to the British Columbia Copper Co. This claim was staked in 1891. The output is about 1,500 tons per day from the Glory Hole, and about 240 men are employed at the mine.

The copper ore obtained here is self-fluxing in the furnaces. From the mine we passed on to the smelter, which commenced its profitable career in 1889. The three present furnaces have each a smelting capacity of 650 to 750 tons per day.

We were told that nowhere in the world are ores containing so little copper (sometimes only one per cent.) successfully smelted without concentration.

Our next visit was to Phoenix, where we commenced our inspection of the Granby Mines. At these mines there is said to be twenty-million tons of ore in sight.

We travelled to the end of the 4,000-foot level at a height of 2,500 feet. The highest altitude of the mine is 5,000 feet. In one of the stopes we met with a surprise as we were suddenly confronted with Mephistopheles armed with a trident and amidst a roar and a smoke his satanic majesty disappeared from our view.

About two tons of dynamite are used daily in the mines and the output was expected to reach one million tons for 1908.

Each visitor was presented with a copper cup as a souvenir and after a most pleasant visit we left for Grand Forks en route for Nelson, and a call was made at the Bonnington Falls for the benefit of some members of the party to take snap shots.

From Nelson we took passage by the Kuskanook, and the charm of the scenery and the rest after the hurry of the last few days was as one member said a sort of Paradise.

At Ainsworth we called to see the Blue Bell Mine and the concentrator, which is under the management of a past president of the Canadian Institute, Mr. S. S. Fowler. This mine is one of the oldest in the Kootenays, having been worked by the Hudson Bay Co. 85 years ago for the purpose of getting ore to manufacture into bullets. The mine is now a low grade lead-zinc property.

Returning to Nelson we were entertained on board by Mr. Leslie Hill, Chairman of the local Reception Committee, and others, and afterwards at the club by the members, leaving later in the day by train for West Robson, where we again took steamer and landed the following afternoon at Arrowhead, and again entered our cars which had been ferried right up the lake.

En route for Vancouver, we passed the newly-developed coalfield at Nicola, and many other interesting mining features whilst steaming down the side of the turbulent Fraser River, which in some places almost fights for the small strip of land appropriated by the railway track. Vancouver was reached on the 21st, and with little delay we again took ship and arrived at Victoria at the far end of our western trip in the dark. The next day was devoted to a meeting of the Canadian Institute in the Parliament Buildings and the reading of papers, receptions, etc.

It has been reported that coal had been discovered under the city of Victoria, but we heard nothing and saw no borings during our stay.

After the preceding day's enjoyments and rests we left Victoria with much regret on Thursday, the 26th of September, by the Esquimaux & Nanaimo Railway, constructed and at one time owned principally, if not entirely, by the Dunsmuir family. On parts of the route hereabouts the scenery is very fine, and reminded us of parts of the Rocky Mountains.

Unfortunately time only allowed a very short stay at the Tyee Copper Co.'s smelter. This smelter has paid good dividends and the mechanical arrangements to save cost were said to be in some cases unique. The element of time again interfered with any chance of visiting the metal mines from which the Tyee Smelter receives much of its ore.

At Ladysmith the Dunsmuir family have large interests and here there is an ample provision for the quick shipment of coal from large bunkers on the side of the quay. Here, as also at Nanaimo, the railway trucks are loaded at the collieries and then ferried across to the mainland on huge scows, towed by a tug. The Ladysmith mines (coal) are not close to the port, but were passed by further north on the way to Nanaimo.

It may be remarked at this point that there is great demand for Asiatic labour, mainly Chinese and Japs, both on the surface and also underground at the mines on Vancouver Island. A Jap can be put to work which a white man will not do, and, therefore, it is clear that the Jap is a greater menace to white labour than is the Chinaman. Already there are thousands of Japs in the city of Vancouver.

On arrival at Nanaimo we were met by the Mayor, the local committee and the staff of the Western Fuel Co., with their chief, Mr. Thos. R. Stockett, and many other influential people. Some of our party visited other collieries whilst others went to the Hamilton Powder Co.'s works under the guidance of Mr. Burnham.

Just after the Western Fuel Co. took over the collieries the whole of the plant at the No. 1 or Esplanade Colliery, was destroyed by fire, and, therefore, the newer erections are quite up to the most modern practice for the economical handling of the output. The Headgear is of wood and about 80 feet high to the pulley centres.

The Brechin Mine was also visited, but the Colliery on Protection Island could not be brought into the programme. The thing that probably struck most visitors was the thin cover which separated the mines from the sea, especially at the Brechin pit or incline. The No. 1 Mine is 610 feet deep. Ventilation is secured by a Cappell fan of 11 feet 6 inches diameter, and at the No. 1 a Sirocco fan of 300,000 cubic feet capacity is being put down to replace a Guibal fan of 36 feet diameter. The output is about 700,000 tons per annum. Coal cutting machines are in use at these mines. The first seam is 7 feet thick, and No. 2, which is 70 feet lower,  $3\frac{1}{2}$  feet thick.

The city entertained us at dinner in the evening. Each visitor was presented with a pretty metal ash tray on which is shown the local Bastion and the word Nanaimo, as a souvenir of this enjoyable visit. After a good night's rest we were disturbed at an early hour and left this hospitable island at 7 o'clock by the s.s. "Charmer." We arrived at Vancouver, where we were met by the Provincial Mineralogist, Mr. W. Fleet Robertson, who had only just returned from his annual trip of exploration into the wildest parts of the interior.

We then drove around the city in automobiles, and were afterwards entertained at the Vancouver Hotel by the City Corporation, Board of Trade, Stock Exchange and resident members of the Canadian Mining Institute, at which 300 persons were present, and we started on our return homewards by train, leaving at 5.15 p.m. The events of our journeyings were discussed on the train, and at Revelstoke four of our party, including myself, had to take a regretful leave of the rest of the party, and thus miss the grandest of the magnificent scenery through the mountains, the Bankhead coalfield and the cattle ranching display at Calgary. I may, however, remark before closing that the Bankhead Coalfield is a very remarkable one, although I did not visit it, for I am told that the coal lies folded in by Carboniferous limestone, that is to say, there is a limestone as a base and limestone as the surface.

Thus came to a conclusion one of the most enjoyable trips a man could possibly have, accompanied with kindred spirits and every reasonable information on everything there was to be seen, and as to the country wherever we happened to be.

On my return, via Nelson, through the kindness of Mr. Irving and others, I visited the Canadian Zinc Com-

pany's Smelter, at that place, from which great results are anticipated. The electrical power is supplied from Bonnington Falls, and the Company hoped to be producing from 4 to 5 tons per day at an early date. I am glad to note from the Canadian Mining Journal, dated February 1st, that this smelter is now treating ten tons of ore per day, and having passed the experimental stage, the Company are intending to increase its capacity to 30 tons a day, the ore so far treated has averaged 10 per cent. of zinc, 10 per cent. lead, 12 ozs. of silver and 1.5 per cent. of copper per ton. This smelter will prove a great boon to the district, as in the past the Mining Companies have been greatly handicapped on account of the ores containing such a large percentage of zinc, consequently metallic mining in this district will be greatly increased.

I also inspected the Westmont Silver Mine, situated up Ten-Mile Creek on the east side of Slocan Lake.

Mr. Griffiths informed me that single-handed for many years he drove the tunnel and passages into the mountain, at first with no satisfactory results, when after great expenditure of time and labour he at last struck ore. With the financial assistance of a gentleman at Toronto, the further development is proceeding

and in the near future a successful mine will be, in all probability, established. I may mention that this mine is situate 5,400 feet above sea level. The ore produced up to the present time has more than paid for development work and has yielded from 150 oz. to 438 ozs. of silver to the ton.

Eventually after further extended journeyings on the American Continent I returned home, via New York, greatly improved in health and my mind enlarged with many useful facts and recollections of a hospitable people and their surroundings, which will last as long as memory remains.

Whatever I may have said regarding the resources of the Dominion of Canada is quite inadequate to convey a true impression of the greatness of this part of our Empire, and to those who are interested I strongly recommend a personal visit.

I conclude by again stating that I received the greatest courtesy from the members and officials of the Canadian Mining Institute to whom I tender my hearty thanks and to my colleagues for electing me as their representative, and my desire is that Canada ever continue to be an integral part of the British Empire.

## WANTED—AN INVENTORY OF PROMISING MINERAL CLAIMS.\*

R. W. Brock.\*\*

In the admirable address delivered by Mr. Marriott at the banquet to the visiting mining engineers at Vancouver, last autumn, he outlined a scheme for acquiring a record of the location of pay grade ore in new districts by a system of bonusing the prospector who gives notice of such an occurrence after the find had been inspected and certified to by a responsible officer. This recalled a suggestion along somewhat similar lines I made to this Institute a decade ago. As this now has the endorsement of so experienced an authority in these matters as Mr. Marriott, I venture to again bring the subject before the Canadian Mining Institute for consideration.

For a rapid development of the great mineral resources of the country—and for a great part of Canada the mineral development is the necessary precursor of the development of its other resources—there are three outstanding needs, an army of real prospectors, a large corps of well-trained professional experts, and capital. Unless there is a sale for prospects you will not have an army of prospectors; unless there are engagements for them, you will not have a large corps of professional men; so that the primary need would seem to be capital. A great deal is, therefore, said about the need of foreign capital to develop our mineral resources. But there is money here in Canada available for this purpose, if you can only call its attention to promising prospects. If we have our own money finding profitable investment in mining lands, we shall not need to raise our voices very loudly to turn foreign capital this way. It will come whether we want it or not.

We have in Canada magnificent opportunities for the investment of capital in mining enterprise, in small or large amounts. We all know that, but if, say, our secretary is asked by capital to point out a good investment, he will probably be forced to give a general answer, such as around Cobalt or in the Boundary Creek district. If the capitalist, acting on this advice, sends his representative to the camp to look up such a property, there is a strong probability that his time, his patience, his endurance, and possibly his money, will be exhausted looking over wildcats, and he will depart without doing business, under the conviction that nothing good is in the market. The investor needs some certain and expeditious way of getting track of suitable properties to develop.

On the other hand, the prospector's work and life cuts him off from "connections." He has little opportunity of meeting possible buyers, and seldom knows how to bring a deserving prospect before the notice of bona fide investors in such a way as to interest them. The company's engineers on the lookout for prospects have been on too many wild goose chases to be much impressed by a new prospector's tale, should the prospector by any chance happen to get an opportunity to relate it. So that, except on the crest of a boom, a prospector has great difficulty in disposing of his claim. No matter how good, it is of no use to him or to the country unless he can get in touch with money that will take it over and convert it into a mine. The prospector, therefore, stands in great need of some medium whereby his claim will be brought to the attention of development companies. This is particularly necessary in Canada, where the majority of the ores are low-grade, and the natural difficulties too heavy for any prospector to overcome. The great need, therefore,

\*Paper read before the Canadian Mining Institute.

\*\*Director of the Geological Survey of Canada.

seems to resolve itself into some method of introducing the man with capital to the man with the promising claim.

My suggestion was that there should be local centres, such as boards of trade, mining recorders' offices, local branches of the Canadian Mining Institute, etc., at which a prospector could file a statement, giving an exact description of the location of his claim, which would enable one to find it, an address by which he could be reached, the dimensions of his ore body so far as determined, the character and value of the ore, the terms he would accept, etc. Statements regarding dimensions and value might not be very convincing if made by the prospector himself, but if in the form of a certificate from a responsible disinterested technical man, they would be valuable, and, if favourable, would be sure to attract investors.

Copies of the statements on file at the local centres could be forwarded to the Provincial Department of Mines, and from the Provincial Department of Mines copies could be secured by the Federal Department of Mines, and by the Secretary of the Canadian Mining Institute. Such information at accessible points would be invaluable to the company or individual looking for investments.

The cost to the prospector of having his claim sampled is perhaps the chief obstacle in the way of the successful operation of such a scheme. If once under way, the certainty of attracting buyers would probably induce prospectors to use every effort to get "into the game." To help out the prospector on the financial side, mining engineers might do this work, when convenient, at a special rate, for the existence of such lists would be of great value to them. Assayers, particularly in provinces where they are licensed, might also be used by prospectors to acquire the information and furnish certificates. For the certificate of a responsible assayer with a reputation to maintain, that he had visited a property, found an ore body of such-and-such dimensions, sampled it carefully, and found that his samples representing so many feet of vein yielded such-and-such values, would be sufficient evidence of the worth of a claim to justify an inspection by a would-be investor.

A further inducement to prospectors to have such a report made on their claims might be given by allowing the cost of the examination to count towards the annual assessment, just as in British Columbia the cost of surveying a claim is accepted in lieu of assessment work.

Such an examination would benefit the prospector in many ways. A technical man on the spot could give the prospector valuable advice as to the most effective way of opening up and proving his claim. A concrete demonstration on his own ground would do more for the prospector than any number of text-books or mining classes. Most prospectors need and would welcome such assistance. It is pathetic to see a sincere and energetic prospector spending his few sweat-earned dollars and the best years of his life doing work on his prospect that is not developing it, but is detracting from rather than adding to its market value. This country cannot afford to have that man's energy and effort wasted. It's far too valuable. It should be directed so as to secure definite results, to prove that here is or here is not a valuable piece of ground. Prospectors may not always be ready to accept advice when they get it free, but a person sets greater store by something that he pays for.

The examination and report would be valuable to a prospector in helping to describe whether his claim was worth further attention or not, and the sooner a prospector can discover this the better. If good, he will go at the development with greater vigour; if bad, the sooner he finds it out and hitches up to a new claim the better.

Not every good claim would yield attractive returns if sampled in the early development, but it will usually have some earmarks which would encourage the prospector to stay with it. We know, of course, that the faith which removes mountains may sometimes make a mine out of a discarded claim, but the man with that faith is not going to be staggered by an adverse report.

Altogether, the prospector will find such a report a good investment. Development companies would find the lists a great boon. Indeed, I fancy if such lists were available, a large number of development companies would be formed to go in for this most profitable business. Proved properties, the product which the development companies would place on the market, are what foreign capital is looking for.

#### DRAFTS IN STEAM BOILER PRACTICE.

In a preliminary bulletin issued by the U. S. Geological Survey, many important facts concerning steam-boiler practice may be gleaned.

Experiments made seem to indicate that it is possible to double or treble the capacity of a plant without making any radical changes in the furnaces and boilers. These increases require about double and treble the quantities of air to be put through the fuel beds and boilers. It is also probable that rebaffling the boilers will often permit the capacity to be doubled or trebled, while still getting more steam than formerly per pound of coal for uses outside the boiler room.

The experiments were undertaken with the object of clarifying ideas concerning the passage of air through fuel beds and boilers. Measured weights of air were passed through two beds of lead shot, in series, one of which remained always the same and represented a boiler; the other being varied as to size of shot and depth of bed, and represented a fuel bed. Careful observations were made of the weight of air passing through the beds per minute. All data were plotted in many charts, so as to permit the study of them from several points of view. A number of laws were deduced bearing on the relative amounts of power required to force air through fuel beds of various thicknesses, composed of various sizes of coal, and through boilers of various lengths and areas of gas passages.

It may be possible, as a result of these investigations to raise the rate of working the boiler heating surface to three or even four times its present value. Such an increase would undoubtedly mean new designs of grates, furnaces, and boilers, especially fitted for high rates of working.

At the Zinc Corporations' works, Broken Hill, New South Wales, during January, 1909, 16,560 tons of zinc lead tailings were treated in Elmore vacuum plants, succeeded by Wilfley tables. The original dumps contained 20 per cent. zinc, 5.7 per cent. lead, and 8 ounces silver, per long ton. The "vacuum" concentrate assayed 43 per cent. zinc, 11 per cent. lead, 17 ounces silver. A recovery of about 90 per cent. of the zinc, 73 per cent. of the lead, and 85 per cent. of the silver was shown. The average cost of the whole treatment is given at 5s 7d per ton.

# THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

By F. W. Gray.

(Continued from issue of March 15, 1909.)

The mine at the present time has natural ventilation. The foundations for the permanent fan are constructed, and the fan race and air shaft are both complete. The air shaft is 10 ft. by 14 ft., and is concreted for the entire depth, 50 feet from the surface. The centre of the shaft is 32 feet from the centre of the fan, the small offset being concreted up to the fan discharge. The fan will be a Walker "Indestructible," 11 feet diameter, with a rated capacity of 150,000 cubic feet per minute, with 2-inch W.G. It will be driven by a Walker engine, non-compound, cylinders 14 inches by 30 inches, with 2 feet 6 inches stroke. The power will be transmitted by rope drive, five 1½-inch cotton ropes. The fan itself will be cased in steel and concrete. The house for the engine will be of

the bankhead by the haulage rope, and will be conveyed to the tipples by means of car pullers, which consist of an arrangement of chains and hooks. Passing out of the tipples the cars are automatically "kicked back" towards the mine, and are drawn by empty car-hauls to the brow, where they are made into trips and lowered once more on to the haulage rope. The coal is dumped by the tipples into hoppers, from which it is slowly fed on to a double battery of shaking screens, passing thence to two picking belts 5 feet wide and 40 feet long. From the picking belts the coal is passed on to a loading belt, which deposits the coal into the railway cars by means of a lowering "jib," thereby avoiding any breakage due to the fall into the cars. The screening plant is to be driven by a 12-inch

Dominion No. 12—Bankhead in Course of Construction.

entirely fireproof construction. The whole arrangement will be similar to that recently put in at No. 6 and previously described.

The haulage for some time to come will be effected by a 14-inch by 20-inch Jenckes hoist, which was formerly in use at No. 6. Later, when the mine is more developed, a more powerful haulage engine will be put in, space being reserved for this in the general layout.

The bankhead, which it is expected will be completed in time for the opening of the 1909 shipping season, will be a semi-fireproof structure, built on concrete piers, with hard-pine timber-frame, concrete floors, and corrugated-iron siding and roof. The structure will be 560 feet long from the slope mouth to the centre of the picking belts, making the over-all length 610 feet. The main portion of the bankhead will be 32 feet across, and the picking belt house will extend sideways for a distance of 75 feet.

Trips of 30 cars will be hauled from the mine on to

12-inch Goldie-McCulloch engine, by means of shafting with manilla rope drive. The screening arrangements generally are very similar to those previously described at No. 5, 6 and 7 Collieries.

The colliery shops are more than usually complete because of the outlying position of the new collieries with relation to the Central Shops at Glace Bay.

The Machine Shop is a timber-framed building 30 feet by 48 feet long, covered with steel shingles. It contains a 24 in. by 16 ft. lathe, 25 in. shaper, 25 in. drill press, 8 in. pipe threader, small bolt and pipe threader, grinding machinery, etc., all driven by a 6 by 6 Robb engine.

The Forge and Carpenter Shop are in one building, timber frame covered with steel shingles, separated from each other by a 12 in. fire wall, equipped with underwriters' fire-door. Each shop is 30 ft. by 36 ft.

The Forge contains six brick forges and a 250 lb. Niles steam hammer. A Buffalo blower supplies the

forced draft. The Carpenter Shop is equipped with cutting-off and rip saws. A 6 in. by 6 in. Matheson engine drives the saws and blower.

The Warehouse is a 30 ft. by 60 ft. frame building, two stories.

The Wash-house is 60 ft. by 30 ft., and has 120 lockers. These, as will be seen from the photo, are of novel construction. The lockers are constructed with a skeleton framework and stout wire netting, with

constructed near the colliery by impounding the waters of Irish Brook, which flows into Barachois Pond, and it is intended to supply all the water required for the colliery and domestic use of the Nos. 12 and 14 Collieries. The pumping station at the dam is equipped with a 600 gallon Worthington compound-duplex pump, and will supply the two small colliery receiving reservoirs and the houses. The colliery reservoir at No. 12 will hold 750,000 gallons.

Dominion No. 12—Carpenter and Forge Shops.

steam coils underneath. The open network gives the building an airy and cleanly aspect, and everything being in full view, the accumulation of dirt or rubbish will be prevented, and there will be no danger of fire from contact of the steam coils with wood. The usual hot and cold water taps and hand basins will be provided.

The Lamp-house is a small structure, 16 ft. by 33 ft., equipped at the present time with 140 Ackroyd & Best

The fire protection water service consists of a 500-gallon approved underwriters' fire-pump situated near the boiler-house. The water supply is drawn from the small reservoir, and is connected by 1,400 feet of 6 in. fire mains supplying seven hydrants placed at all necessary points.

**No. 14 Mine.**—These slopes are situated a mile east of Dominion No. 12 on the same seam, and have been driven 600 feet down from the surface. The pitch

Dominion No. 12—Exterior of Wash House (to left hand) and Lamp House.

safety lamps, which have been used since an early stage in the mine development.

Other structures are the stables and two small oil-houses.

An office is being built to serve both No. 12 and No. 14 Collieries. It is a frame building 32 ft. by 24 ft., and contains a fireproof vault for the storage of papers.

The water supply is an adequate one. The main reservoir, with a capacity of 7,200,000 gallons, has been

of the seam is about the same as at No. 12. The plant is as yet only temporary, and no permanent structures have been commenced. The surface equipment of the mine will not be so extensive as that of No. 12, as many of the erections at the last-named place will serve the two collieries. Permanent construction work will not be undertaken until the summer of 1909.

Most of the work on the sites of the new colliery villages is well under way. The houses at present

under construction number 18, and 53 are already built and tenanted. In addition to this it is anticipated that 70 houses will be built in 1909.

**Other Coal Areas.**—In addition to the areas already described in detail in the Glace Bay and Langan-Victoria Basins, the Dominion Coal Company have large coal areas under lease at other points. In the Morien Basin they own the old Gowrie & Blockhouse property, covering six square miles, and also five square miles underlaid by the Tracey Seam near McDonald's Lake, near the edge of the coal measures of the Morien Basin. They own, also, thirty-five square miles of submarine coal leases under the waters of Cow Bay and Mira Bay.

The Dominion Coal Company further own twenty-five square miles of submarine coal areas situated near Point Aconi in the Sydney Mines Basin, to the north of the areas now being worked by the Nova Scotia Steel & Coal Company, which are underlaid by all the workable seams of the Sydney Mines Basin. These areas are virgin, and they constitute a coalfield not much inferior in value to the Langan-Victoria areas

### Summary.

### THE WIDENING OF THE COBALT SILVER BELT.

Written for the Canadian Mining Journal by Frank C. Loring.

Cobalt proper, or that portion of Coleman and Bucke Townships embracing the three or four square miles of territory which is the producing area, has steadily increased its production, as well as its reserves. Probably 1909 will show a large increase over 1908. Reserves have increased as well as probabilities from future development. Exploration, especially at depth,

Dominion No. 12—Miners' Wash House, just before completion. Shows Clothing Lockers and Tables for Wash Basins, Taps, etc.

just mentioned. At this point the dip of the coal seams is about 6 per cent., or the same as that of the submarine seams of the Glace Bay Basin. The Coal Company's leases extend from the shorecrop of the Black-rock Seam near the Great Bras d'Or entrance for a distance of nine miles along the shore round Point Aconi to the edge of the N. S. Steel & Coal Company's holdings at Little Pond.

The Coal Company also own a submarine area off Cape Dauphin which bounds the areas of the New Campbellton Colliery.

The following summary of the coal contents of the areas controlled by the Dominion Coal Company was prepared by the late Dr. E. Gilpin in 1902, at which time Dr. Gilpin was Commissioner of Mines for Nova Scotia. No seams under three feet in thickness are included, and in making the calculation Dr. Gilpin stated that "the usual uniformity, regularity and freedom from faults of the strata and coal beds of this district permit of exceptional confidence being placed in any estimate of coal contents."

has been in several instances most important, and gives additional evidence that the district will be long lived.

Far greater attention is being paid to ores of lower grade, not of sufficient value to market crude but desirable for concentration. Undoubtedly there are extensive bodies of this class of ore which should yield large profits. The extent of these bodies of so called low grade ore is the best evidence of the strength of many of the veins, and, consequently, proof of their probable longer life in many cases.

Stimulated by the success of Cobalt, during the past two years there has been extensive prospecting both northwesterly and southeasterly, notably along the Montreal River near the present town of Elk Lake, near Maple Mountain, at South Lorrain, twenty miles south-east of Cobalt, and during the past year in the Gowganda and Miller Lake districts westerly from Elk Lake from twenty to thirty miles. Prices have often been greatly inflated, and, consequently, disaster and a probable reaction in sentiment will often result. Nevertheless, purely from a mining standpoint without

considering these artificial conditions, extraordinary effort is being made to develop these various districts and to ascertain their true value.

What is perhaps more extensively criticised than anything else in the development of prospects in that region, is the quantity of machinery ordered and installed before extensive prospecting has been done. This is in many cases for the purpose of boosting mining shares already marketed. Nevertheless, there is often good reason for this. What especially characterizes mining in that region as compared with other districts is the quantity of possible ore bearing veins. So long as any vein remains unexplored, no matter how small, there is warrant for additional work. A few tons of high grade ore return all expenditure. Consequently with the task set, the reasonable method is often to put in machinery.

Although surface trenching is desirable, in order to ascertain the number and extent of possible ore bearing veins, it has become more and more the practice to develop at depth rather than at the surface. Sometimes a mere crack when followed opens out into a profitable ore body. With dozens of these cracks known, there is often no other reasonable way than to attack the problem with a reasonable amount of machinery. Consequently criticism is often unjust.

Acting largely on this theory, a number of power plants have been or are being installed in the Montreal River district, at South Lorrain, and Gowganda and Miller Lakes. In the Montreal River, the Mother Lode Otisse, Otisse Currie, North American Silver Mining Company, Moose Horn, Elk Lake Development Company, as well as others, have installed power plants. In South Lorrain the Keeley Mine has an elaborate gas producer plant, the Wettlaufer is installing a five-drill compressor, and other companies contemplate the erection of machinery. At Gowganda and Miller Lakes I know of eight plants that are being installed, ranging in capacity up to ten power drills. Elsewhere, as at Maple Mountain, are other plants. In fact, outside of Cobalt proper there must be thirty or more installations of machinery, costing from \$10,000 up. Many of the mining companies have provided supplies for several months' operation. The old policy of stopping as soon as silver is discovered and waiting for a buyer has been generally abandoned for one of energetic effort to ascertain the true nature and extent of the ore bodies. This must result in enormous increased development, and, in fact, already there are evidences of this probability. It would not be at all surprising if the Cobalt region and its outlying camps double last year's production during the present year.

## REPORT OF THE DEPARTMENT OF MINES, PROVINCE OF NOVA SCOTIA, 1908.

(Continued from last issue.)

### CUMBERLAND COUNTY.

**Eastern Coal Company, Limited.**—This company's collieries at Maccan have made good progress during the year. Mine development has been pushed. Sinking has been continued to a total depth of 1,132 feet from the surface. A nine-million gallon reservoir was among the additions to the surface plant. Bankhead, screens, picking belts, engine and other machinery are complete. **The Joggins Mines** belong to the same company. Noteworthy changes have taken place here. A new slope, 2,400 feet, has been driven, and a new bankhead completed within thirteen months.

The other coal mines of Cumberland County are the **Chignecto, Strathcona, Jubilee, and Fundy.**

**The Debert Mine**, Colchester County, has a small output. It is, however, being developed rapidly.

### PICTOU COUNTY.

**Acadia Coal Company.**—The **Allan Shafts**, Nos. 1 and No. 2, of this company have been connected and ventilation thereby improved. Endless haulage was installed for conveying coal from No. 2 shaft to the new bankhead at No. 1 shaft. **The Albion Mines, Acadia Colliery, and Vale Colliery**, all operated by the Acadia Coal Company, have shown much improvement. The mining practice at these collieries is modern and effective. Safety lamps used are of the Wolfe Patent Lighter type, with magnetic lock except at their Thorburn mine, where the Ackroyd-Best is soon to replace all other makes. Saxonite and Monobel are the explosives utilized.

**Intercolonial Coal Company, Westville.**—The **Drummond** collieries report a fair amount of develop-

ment. New seams have been discovered overlying the main seam south-west of Stellarton.

**Marsh Colliery, Coalburn.**—This mine shipped 35,033 tons of coal during the year. 65 men are employed underground.

### Accidents in Collieries.

Year ending September 30, 1908.

|                          | Fatal. | Non-Fatal. | Total. |
|--------------------------|--------|------------|--------|
| Cape Breton, South ..... | 14     | 126        | 140    |
| Cape Breton, North ..... | 6      | 20         | 26     |
| Cumberland County .....  | 4      | 3          | 7      |
| Pictou County .....      | 5      | 24         | 29     |
| Inverness District ..... | 13     | 10         | 23     |
| Totals .....             | 42     | 183        | 225    |

Total number of workmen under and above ground, 14,547.

Fatal accidents per thousand men employed under and above ground, 2.887.

Non-fatal accidents per thousand men employed under and above ground, 12.58.

Total coal produced, 6,299,282 tons.

Coal produced per fatal accident, 149,983 tons.

It may be remarked here that the reports of accidents are most unsatisfactorily arrayed. No general tabulation is given. There is merely a list of unclassified accidents for each district. It is certainly time that the department realized the absolute necessity of presenting clear analytical tables. The above statement has been prepared hastily from the lists in the Report. The special reports upon the Port Hood Explosion are not creditable documents.

**GOLD.**

During the year ending Sept. 30th, 1908, the production of gold in Nova Scotia fell to 11,990 ounces—8,016 ounces less than the previous year. This amount was recovered from 59,797 tons of ore crushed, representing an average of 4.02 dwts. from each ton treated. This yield per ton is practically identical with that of last year; but the total production is the smallest since 1881.

No serious accidents occurred during the year. Deputy Inspector Picking's remarks are as follows:—

"Fourteen different companies were operating in the following districts: The Beaver Hat Gold Mining Co., at Lower Seal Harbour; the Boston Richardson Mining Co., at Goldboro; McDonald & Copeland (Mod-

ince, among which were County Harbor and Miller's Lake, in Guysboro County, West River, Sheet Harbor, Harrigan Cove, Lake Catcha, and Montague in Halifax County, Gold River, Lunenburg County, Rawdon and Uniake, in Hants Co.

"Exclusive of tributors and prospectors, the industry provided employment for 500 men; this being about the same number as during the previous year.

"At Caribou, Renfrew, Malaga, Gold River, and Middle River, development and construction work claimed the attention of the operators, and during the coming year a large increase in production should be received from these districts.

"At the Boston Richardson, although the mill and bromo cyanide plant were in almost continuous opera-

stock) at Forest Hill, all in Guysboro County; the Dominion Mining Co., at Tangier; the Caribou Gold Mines, at Caribou; the Consolidated Mines Co., of Canada, Ltd., and the Robert Kaulbach Mine, (Touquoy), at Moose River; the Oldham Sterling Mining Co., at Oldham, all in Halifax County; the Chester Basin Gold Syndicate at Gold River; the Mic-Mac Gold Mining Co., at Leipsigate, both in Lunenburg County; W. J. Prisk & Co., (Malaga Mining Co.), at Malaga Barrens; the Ophir Gold Mining Co., at Brookfield, both in Queen's County; the Eagle Mining Co., at Renfrew, Hants County; and The Great Bras D'Or Gold Mining Co., at Middle River, Inverness County, C.B. In addition to this, tribute work and prospecting was carried on at many of the other districts throughout the Prov-

tion, the larger portion of stuff milled was from the development work on the new incline shaft, and the 550 and 700 feet levels.

"The operations of the Great Bras D'Or Gold Mining Co., at Middle River, are of special interest, and the past year shows the first gold recovered in this district, or in fact in the island of Cape Breton, by stamp milling. The method of mining here, namely, tunneling into the base of the hill, and thereby doing away with hoisting and pumping, should enable the operators to supply the crusher with ore at an exceedingly low cost. At the Oldham-Sterling mine, the steady increase of values gotten from the Sterling barrel-lead as depth is attained, is very gratifying.

"Operations of the Boston Richardson Mining Co.,

were interrupted for a short period during the past year owing, it is said, to need of financial adjustment, after a very short delay the mine again resumed work with a fair prospect of business success.

"A feature in the operation of this company during the past two years has been the attention paid to arsenic extraction. Arsenic in greater or less quantities is found in nearly all of the gold bearing leads of the province, and the results obtained by the Boston Richardson Mining Co., should encourage other companies in the province to give the extraction of this mineral serious attention.

"The introduction of hammer drills into many of our mines should greatly reduce cost, especially in working narrow belts where the introduction of the hammer drills will enable the mines to be worked at a profit; where this was not possible when using the piston drill or the slower hand-steel. Two kinds of drills are at present in use in the province, namely, the Murphy, manufactured in Denver, and the Whitcomb, manufactured in Rochell, Illinois. At the Mic-Mac mine, before purchasing hammer-drills, competitive tests were carried on; the hammer drill competing against the piston drill. In one shift, with the hammer drill 106 feet were drilled and fired by one man. In actual drilling time, 2 hours, 35 minutes, 42 feet 6 inches were drilled, holes all uppers. These drills are now being used by the Mic-Mac Gold Mining Co., The Eagle Mining Co., The Chester-Basin Gold Syndicate, the Oldham Sterling Gold Company, and the Caribou Gold Mines.

"A most important discovery of tungsten in the form of scheelite was made at Moose River gold district, early in the summer: reference will be found to this in another page of this report. Although the gold production for the last year has been somewhat unsatisfactory, indications, at the end of the year, point to great activity and increased production during the year 1908-09."

#### TUNGSTEN.

The discovery and exploitation of the scheelite deposits near Moose River have been described already in the *Canadian Mining Journal*.

#### GOVERNMENT DRILLS.

The Government of Nova Scotia is liberal in its use of diamond and calyx drills. During the year five drills were kept in commission at a cost to the Department of \$4,690.40; 22 holes were bored, making a total footage of 7,905 feet 7 inches. This exceeds the previous year by 1,632 feet 6 inches, and constitutes a record for the Province. Costs were brought down satisfactorily. The figure given above is not total cost, as the Department only meets a part of the expense. Since the year 1900 the Department has expended \$65,372.92 in connection with these drills.

The average actual cost per foot for boring by all drills was \$1.06. The cost per foot for all boring by diamond drills was \$0.805, and by calyx drills, \$1.34. The carbon cost per foot in boring by diamond drills was \$0.077, and the shot cost per foot by calyx drills, \$0.056.

The report of Mr. Harry Piers, curator and librarian, on the Provincial Museum and Science Library, bring the volume to a close. Mr. Piers, who was in charge of the Nova Scotia mineral exhibit at the last Canadian National Exhibition, reports 117 accessions

to the Museum, and the addition of 3,761 pamphlets and books to the library.

Appended to the Annual Report are statistical tables.

#### COMPOSITION OF THE APLITES.

Written for The Canadian Mining Journal.

In view of the ever-increasing interest in the aplite of Northern Ontario, it was thought that the following results of chemical analyses of some of these, made by the writer, might be of interest to some of your readers

|                                | I.    | II.    | III.   |
|--------------------------------|-------|--------|--------|
| SiO <sub>2</sub>               | 78.28 | 58.84  | 72.33  |
| Al <sub>2</sub> O <sub>3</sub> | 12.00 | 11.24  | 12.99  |
| Fe <sub>2</sub> O <sub>3</sub> | ....  | ....   | none   |
| FeO                            | 1.19  | .475   | 2.50   |
| MgO                            | .37   | .35    | .97    |
| CaO                            | .29   | 12.17  | 1.73   |
| Na <sub>2</sub> O              | 6.89  | 6.91   | 7.60   |
| K <sub>2</sub> O               | none  | .07    | none   |
| H <sub>2</sub> O               | .61   | .40    | 1.09   |
| TiO <sub>2</sub>               | .34   | .26    | .74    |
| CO <sub>2</sub>                | none  | 9.84   | 1.00   |
| BaO                            | ....  | none   | ....   |
| S                              | ....  | .13    | ....   |
|                                | 99.97 | 100.68 | 100.95 |

I.—Typical, fine-grained, pink aplite, in which no calcite could be detected, from Foster Claim, James Township.

II.—Typical, fine-grained pink aplite, showing considerable calcite, from 444 James Township.

III.—Grey, medium-grained granite, with a little calcite, from the dike cutting diabase on the University property, Cobalt.

Under the microscope all three show mainly acid plagioclase and quartz with a little titanite and chlorite, and in II. and III. some calcite.

The analyses show that the acid plagioclase is necessarily albite. The proportion of the mineral constituents of each is therefore easily calculated and shows:

|          | I.   | II.   | III.  |
|----------|------|-------|-------|
| Albite   | 58.4 | 59.0  | 64.4  |
| Quartz   | 36.8 | 16.7  | 26.8  |
| Titanite | .8   | .6    | 1.8   |
| Chlorite | 3.7  | 1.6   | 4.9   |
| Calcite  | 0.0  | 22.4  | 2.2   |
|          | 99.7 | 100.3 | 100.1 |

The table brings out clearly the simple mineral composition of the aplites, concerning which there has been some diversity of opinion. It also emphasizes the similarity of the granite dike on the University property, Cobalt, to the aplites of the Montreal River area.

N. L. BOWEN,  
Geol. Labs.,  
School of Mining, Kingston.

#### GOLD IN APLITE.

In Dr. Malcolm MacLaren's book, "Gold," an interesting occurrence of that metal in aplite is described. Overlying the Archean rocks in some regions of British Guiana, South America, is a great development of unfossiliferous sandstone and conglomerate of unknown

age. Both the Archean rocks and the sandstones are penetrated by dykes and sills of diabase. In places the diabase appears to have been developed as laccoliths. Elsewhere it has flowed over the Archean rocks.

Gold is found widely diffused in the districts occupied by the Archean rocks, but only in payable quantities where certain conditions prevail. Chief of these conditions appears to be the intrusion of basic igneous rocks, which are of two periods. The earlier belong to the gneissose formation, and were probably originally gabbro and diabase, but are now converted to quartz-diorite, epidiorite, amphibolite, and hornblende-schist; while the later igneous rock is an unaltered diabase.

In the former type of rocks, gold appears to be diffused through the mass, and is set free during its weathering and degradation in sufficient quantity to form economically valuable placers.

When the Archean rocks are traversed by dykes of the later diabase, gold is not infrequently found in the decomposition products, especially in the vicinity of the junction of gneiss and diabase. The gold deposits occur most frequently where the dykes of diabase are small and numerous.

A third source of gold, at times of economic importance, is in highly mineralized acid rocks, such as the aplite of Omai. In many places there occur negmatite veins that gradually pass into quartz veins in lateral extension, but these are almost always barren.

The surface rock at Omai is a diabase which is associated with aplite and granitite. Borings to the depth of 964 ft. revealed epidiorite. The Archean rocks of the country are apparently intruded by the mass or stock of aplite granite. After its intrusion there was a succession of outbursts of diabase, and the latter rock is now developed both above and below the aplite. The interest of the occurrence lies in the fact that the aplite is gold-bearing, selected specimens assaying as high as 15 dwts. per ton. The aplite carries at depth a great deal of pyrites, and the gold found is probably associated with that mineral. Small quartz veins, which are exceedingly numerous in the aplite, are slightly auriferous. Most of the gold is obtained by suicing the highly decomposed aplite.

### THE SONG OF THE OIL-WELL DRILLER.

By John Ravenor Bullen.

In that fascinating region where a bark-stripped grey-white legion

Of three-legged ugly derricks streak the sky,  
'Mid the rustle and the hustle of a breath-destroying bustle.

There, for many thrilling years existed I.

Could I give the faintest notion of the crashin' mad commotion

Of a drillin' rig that's reelin' off a "run,"

When the engine gets agoin' and the damned old boiler's blowin',

You would own there's nothing like it 'neath the sun.

When the walkin' beam's abangin' with a demon-devil clangin'

And the rig just settles down into her stride,  
Why you yellow-bellied quitter, you uneducated critter,  
She 'ud make you fairly jump from out your hide.

"Fire the boiler till you bust 'er, bring in well or bring in duster,

We'll jolt 'er down a fifty foot to-day,  
Man alive, screw on that sinker—Good God, Bill, hook out that clinker!

Jumpin' Jordan! pull the wrench block out the way.

"Move them legs you pig's-foot bladder, leap it up that scaffold ladder,

Or I'll use this broncho-bustin' boot o' mine,  
Lock your lips in on that drivell, flap a motion on that swivel,

And we'll jerk the blinkin' sand-pump into line.

"There she goes—ker-plink'ker-sploser, swishle bur-rur-rur-rur swosher,

Brake 'er! brake 'er! there she sits, 'four-sixty-eight,'

Plup—kerthropper—throp—kerthropper, yank 'er out she's packed in proper,

Now lets see the latest 'cuttin's'-up to date.

"Up she comes arearin', rippin', beat my block, she's fairly drippin'

With the oozy genuine—or I'm a liar,  
Hear the rocked-in gas a-gnawin' at the walls just like the roarin'

Of a bunch o' snortin' engines at a fire.

"Glory boys, here comes the shooter, 30 quarts just ought to suit 'er,

Let 'em down and blow 'er guts up to the light,  
Crack!—thud! 3—5—7—ten—now, keep your—what did—if—it—when—how!

Swish—swish!—God!—it beats a rocket in the night!

"Hallelujah! boys, she's flowin', bubblin', bellowin' an' blowin'

Like a grampus!—hip, pip, pip, pip, pip, hooray!  
Did some oyster whisper duster? she's a regler blue-jean buster,

Pump a barrel? pump a hundred every day!"

Yes, there's something that will never cease a-calling me—for ever,

I might reason out the wherefore and the why,  
But it's in that wondrous region where a bark-stripped grey-white legion

Of three-legged ugly derricks streak the sky.

Toronto, March 17th, 1909.

## BOOK REVIEWS.

**Millwrighting.** By James F. Hobart. 140 Illustrations, 401 pages. \$3.00 net, postpaid. Hill Publishing Company, 505 Pearl St., New York, 1909.

In the set phrase of the reviewer this book "fills a long-felt need." "Millwrighting" gives a comprehensive view of a subject on the details of which many mining engineers are weak. Beginning with a definition of a millwright the location, foundation, erection and roofing of mill buildings, are described. Much practical advice goes along with the description. Installation of machinery, laying out shafting, putting pulleys in place, belts and belting, setting up machines, babbitting, pipe fitting, etc., are succinctly set forth. Moreover the engineering phases of millwrighting are by no means neglected. Such topics as strength of materials, factors of safety, snow and wind loads, roof trusses, are given proper attention.

Readers of Hobart's volume will be particularly impressed with the wealth of useful hints to be found throughout its chapters. We notice, for instance, that in Chapter XIX two pages are occupied with a description of the preparation and use of glue in the construction of wood pulleys. Similarly, most useful instructions are given concerning shop work.

"Millwrighting" can justly be placed in the category of useful and necessary books. In new districts, where the operator has not the example of neighbors to guide him, it will be found particularly handy.

## EXCHANGES.

**The Mining World, March 27, 1909.**—Our contemporary of this date comments in its editorial columns upon methods employed in dealings on the curb market. The curb is, apparently, attempting to regulate the listing of market shares. The Mining World declares that a mining stock should be thoroughly investigated and that the mine itself should be examined by a mining engineer "who should be employed by the curb organization at a regular salary provided by a small monthly tax on the members."

**The Engineering and Mining Journal, March 27, 1909.**—An editorial on "Coal Mining as an Investment" in this number concludes thus: "For the man whose judgment is sound and vision is keen, coal mining offers attractive opportunities. The cry of over-production is not more serious now than it was in 1902, and along with improved methods of mining, that not only insure cheaper production but also a greater percentage of recovery, the prices paid per ton at the mines are higher now than in 1902. It is to be admitted that labor and material now cost more, but the slight increase in them is offset by the advance in the art of mining, which now enables a recovery of 90 per cent. or more as compared with 70 or 80 per cent. a few years ago."

**Mines and Minerals, April, 1909.**—Mr. Francis Donaldson writes on "Modern Shaft Sinking" in April Mines and Minerals. He refers particularly to the time limit and penalty set in sinking shafts by contract. The usual time limit provision reads: "and in the event of the contractor failing to complete the work by this date, it is mutually agreed that he shall pay the contractor the sum of — dollars for every day thereafter until the work is completed, not as a penalty, but as liquidated damages." In spite of this definition the

courts have often held that the actual damages must be proven, and the possibility of collecting the stated damages is not assured. . . . "The writer therefore believes that where a penalty is to be collected for delay, an equal premium should be paid for time saved, not only because this is fair but also because it is likely to expedite the work."

**The Mining Journal (London), March 20, 1909.**

—A remarkable letter appears in this issue of The Mining Journal. A correspondent writing from Ambositra Madagascar, states that Messrs. Mortgage & Grillon's claims, although worked by very primitive methods, have yielded 233 kilogrammes of gold in less than a fortnight. Since July 1907, it is averred, the output from these claims has reached considerably over two tons of gold. The soft and partly decomposed quartz is collected by the natives crushed between two stones and the residue panned. In this way 20 to 30 per cent. of the gold is saved. From a locality near Ambositra, the writer claims to have seen a piece of mica schist, weighing about 5 lbs., being crushed by native women with small wooden sticks and then panned. The gold obtained was a little over an ounce. The tailings showed that over 70 per cent. of the gold was lost.

## PERSONAL AND GENERAL.

Dr. A. E. Barlow has been ill for some days at his residence in Montreal.

Mr. John A. Macdonald, manager of the Foster Mine, Cobalt, was in Toronto on the 7th inst.

The Hon. Mr. Cushing, Minister of Public Works, Alberta, was in Toronto on April 2nd.

Mr. James Conmee has been appointed chairman of the Commons Committee of Mines and Minerals.

Mr. Albert Scott, well known in Temagami and Cobalt, has accepted a position with the Lake Superior Corporation.

Mr. W. H. Aldridge, manager of the Consolidated Mining & Smelting Co., has been in Montreal in company business.

Mr. Martin Cohn, managing director of the German Development Company, is residing temporarily at 53 Elm Avenue, Toronto, Ont.

Mr. R. L. Broadbent, of the Canadian Geological Survey, is on a trip through the Boundary and Kootenay districts of British Columbia.

Mr. W. A. Carlyle, consulting engineer of the Le Roi Mining Co., is in London interviewing the directors regarding the future development of the Le Roi.

Mr. Norman Fraser, late Chief Inspector of Mines for Alberta, has resigned that position to become superintendent of the Crow's Nest Pass Coal Co.'s Michel collieries.

Mr. E. A. Holbrook, superintendent of the Daly Reduction Company's mill and cyanide plant at Hedley, B.C., has returned from a two months' trip to Massachusetts.

Mr. Fritz Cirkel, M.E., of Montreal, has been retained by a firm of Philadelphia bankers to report on the consolidation of the "King Bros.," "British-Canadian," "Beaver," "Standard" and "Dominion" asbestos mines in the Eastern Townships of Quebec.

## CORRESPONDENCE.

## GOLD MINING IN NOVA SCOTIA.

The Editor:

Sir,—The mention of my name and the incorrect version of my opinions made in the course of a debate in the House of Assembly of the Nova Scotian Legislature renders it proper for me to proffer an explanation and a protest at this time. As the Canadian Mining Journal is the spokesman for the mineral industry of the Dominion, I venture to trespass on your courtesy.

You will be aware that in 1905, at the urgent request of a committee of the Mining Society of Nova Scotia, acting by agreement with the Premier of the Province, I was asked to examine and report upon the gold deposits of Nova Scotia with a view to offering suggestions for successful exploitation and investment of capital. At the time this happened, I was editor of a mining journal, so I declined, suggesting the names of several men better qualified for the task. When, however, I resigned the editorship, I was asked again to undertake the work, it being emphasized that my knowledge of the saddle reefs at Bendigo fitted me to investigate the similar occurrences in Nova Scotia. I agreed to make a preliminary visit, without a fee, it being understood that if the conditions seemed to me to warrant a geological investigation, I would return at a later date and spend a month or more in gathering data. Thus in July, I went to Halifax and in August I returned thither, having accepted the retainer of the Government. The various gold-mining districts were visited and carefully examined, with the assistance of Messrs. Faribault and Weatherbe. No man ever had more capable assistance. Mr. E. R. Faribault is the geological surveyor whose maps constitute the pride of Nova Scotian geology; he is an earnest worker and an energetic observer; if we disagreed, it was not surprising; for to him an ore deposit is a fascinating natural occurrence rather than an economic entity. We disagreed, as scientific geologists and mining engineers are privileged to disagree. I found him optimistic beyond the warrant of facts; doubtless he regarded me as erring the other way. However, he aided me loyally. For Mr. D'Arcy Weatherbe I need scarcely speak; he has become a close personal friend and by his subsequent career he has proved that any high estimate of his character formed by me in 1905 has been more than fulfilled by 1909. Mr. Weatherbe has shown himself to be qualified for positions much more important than that of Assistant Inspector of Mines in Nova Scotia. Thus my work was lightened by cordial assistance, and in September, I returned to New York.

Early in January, 1906, the report was transmitted to Halifax. It has never been published, simply because I took a gloomy view of the future of gold mining in Nova Scotia, more particularly as regards the investment of capital on a large scale. The concluding paragraph of the letter accompanying my report states:

"The conclusion which I formed from the sifting of all the evidence obtained, is that there is a geologic similarity to Bendigo, as regards the form of the gold-bearing quartz, for in both cases the miner has encountered 'saddle reefs' or anticlines of quartz; but there are differences so great between the two districts as to destroy the economic value of the structural likeness. The occurrence of ore capable of yielding a reasonable profit, say, a stoping width of 6 or 8 dwt. per ton, is so scanty in Nova Scotia as to render invidious the com-

parison with Bendigo; and, as far as is known, there is no justifiable expectation of such persistence of good ore in depth within the northern goldfield as in that of the Antipodes. Gold mining on a large scale has rarely proved profitable in Nova Scotia, and the likelihood of developing such enterprises has been decreased by the developments of recent years, because these have indicated the improbability of a repetition of ore-shoots in the underlying quartz formations. By ore I mean gold-bearing quartz from which, under existing conditions, a profit can be won. On the other hand, it is my opinion that mining operations on a small scale, carried out by working miners, without the investment of large sums of money either in equipment or exploration, but based upon local knowledge and skilful prospecting, are likely to prove remunerative.

"I do not endorse the attempts made (chiefly by those who spend large amounts of money lavishly, and too often improvidently, in undertakings not founded on careful preliminary investigation) to belittle the local syndicates and parties of lessees who have found and worked most of the profitable mines of Nova Scotia, and I advise that the policy of the Department be so shaped as to encourage this form of domestic enterprise. It is upon such that the future of gold mining in Nova Scotia must depend, as it has done, for the most part, in the past."

The plain fact is that I performed the duty for which I was engaged without delay and in good faith; the Government paid me for advice; I gave it plainly and frankly, as a physician who after a careful diagnosis finds his patient moribund.

The report was pigeon-holed. Then began a farce, the humor of which I appreciated until it was overdone. In the records of the Mining Society of Nova Scotia and elsewhere will be found excuses and explanations for the failure to publish my report. First, it was said that the report was not completed; next, that it had been delayed by the San Francisco disaster; then, that the Minister of Mines had written to me for further advice or information; then that it was unsatisfactory; finally, that it was pessimistic. On writing to Mr. A. A. Hayward, the President of the Mining Society, I was informed that my opinions were fallible, to which I could not but agree. Thus, I was placed in a false position by the lack of frankness displayed by my friends at Halifax, namely, Messrs. Murray, Hayward, Woodman, and others.

On March 15, before the House of Assembly, Mr. Wilcox stated that only an average of 89 men had been employed by the gold mining industry of Nova Scotia in 1908, as compared to an average of 292 in 1905. He added that last year the gold yield has been the smallest since 1881. Thereupon he quoted various authorities who have written on the subject of gold mining in Nova Scotia, and, among others, one who stated that "gold was not a surface metal, but must be followed to the depths to develop it with any degree of success." This sophomoric rubbish was quoted because it was optimistic. Emphasis was also placed on the fact that the Province had won a gold medal at Toronto for an exhibit of gold specimens; as if specimens bore any relation to mines. Mr. Wilcox did not refer to my report, and for that I am grateful. But Mr. Murray, the Premier, referred to it subsequently and so often that he might have saved time by reading the report

itself to his fellow legislators. Instead, he quoted me inaccurately; in fact, in a most misleading manner. While I am aware that such misquoting was inadvertent, it is inexcusable. The Government paid me a handsome fee to prepare a report for the use of those engaged in gold mining in Nova Scotia; are we to infer that only sugar-coated optimistic opinions have any value? I reported for the Government as I would for any other client, frankly, straightforwardly, without circumlocution. They wanted to know; I tried to tell them as best I could. That is all. Why, therefore, this hocuspocus and dodging? I have kept silent for three years; it seems proper to make the facts known.

Yours faithfully,

T. A. RICKARD.

San Francisco, March 25, 1909.

April 2nd, 1908.

To the Editor Canadian Mining Journal:

Sir,—In your issue of March 15 there is a letter from Dr. Coleman in which he criticizes my retention of the old classification of our Ontario clays, and states that in the light of modern geology these old classes, Erie, Saugeen, etc., are no longer useful. In the first place, I would point out that my article was intended as a practical one for clay-users, a class of people who lack the geological training necessary to make fine distinctions. Further, I submit that any classification of anything to be "useful" must be practical, and Dr. Coleman's suggestion that the Erie clay should be called by a number of names according to the various extinct glacial lakes in which it was laid—is decidedly impractical, except to a highly trained geologist.

I realize as fully as does Dr. Coleman that "The so-called Erie clay was laid down partly as boulder clay and partly in several glacial lakes." And as evidence of that I would cite my report on "Clay and the Clay Industry of Ontario," B. of M. Report, 1906, p. 10, which reads as follows: "The Erie clay represents local deposits of boulder clay, which are often so free from stones and gravel, and so largely made up of clay, that it can be used in the manufacture of clay products." Again on p. 11 of the same report I repeat, "The Erie clay then, appears to be only the cleaner localized accumulations of the boulder clay, and was probably formed in the presence of much more water than was the typical boulder clay."

The deposition of the Erie blue clay was one continuous process whether at one place as boulder clay or at another as more sorted material in a glacial lake; and the clay, or really rock-flour, is quite uniform in its chemical, physical, stratigraphical and economic characters, as shown by a description of it in every county in Ontario west of Brockville. Why then should we give up the old and simple term Erie "blue-clay," known to everybody, for a series of obscure names, such as Warren, Algonquin, Iroquois, etc., based on the various extinct glacial lakes in which this clay was deposited? If these clays differed from each other there would be justification in the suggestion, but when these various bodies of clay would only be distinguishable on topographic evidence, an evidence that very few people could apply, it seems more serviceable, and, therefore, "useful" to retain the old name Erie clay.

Regarding the Saugeen clay, he stated that this term is no longer useful, as this clay is not a separate clay from the Erie. He then adds: "It is often only the shallow water accumulation, near the edge of a

glacial lake, and connects up with blue Erie clay laid down in deeper waters of the same lake." Then he states further: "In other cases it is simply weathered Erie clay from which the lime has been leached." This is surely strange. The first theory gives a genetic origin to this clay, as being contemporaneous with the Erie, while the second theory states that it is of secondary origin and resulted from weathering in place, of a previously existing clay. How can both of these be true?

The first theory is not essentially different from mine, which is that this thinly laminated Saugeen clay, composed of alternate bands of clay and sand, an evidence of shallow water, was deposited about the edge of the slowly retreating ice-sheet in its later stages. This theory, I submit, is the more reasonable when we see this clay extending from Kenora, Dryden, Fort William, Sault Ste. Marie, Webbwood, North Bay, Pembroke, Casselman to the St. Lawrence River; and from this line northward as far as any of our Ontario survey parties have reported on the clays. I have seen it myself from Bracebridge to a point one hundred miles north of Lake Abitibi, making a total cross section from south to north of at least 400 miles. It does not seem reasonable to call this enormous area "Only the shallow water deposit near the edge of a glacial lake."

As for his second theory, "That the Saugeen clay is only the weathered top of the Erie, etc.," I claim it is entirely untenable. There is a red-burning clay in Western Ontario, which is only the weathered top of the Erie clay, from which the lime has been hached, and for want of a better name I have called it the Red Top clay, but it is not for a moment to be confused with the Saugeen clay. The Saugeen clay is usually underlain by a layer of sand or gravel two feet or more in thickness, which separates it from the underlying formations. This layer of sand and gravel is the evidence of a break in the character of the deposition at that place, i.e., it is the evidence of a nonconformity. As long ago as 1863 Dr. Dawson recognized this point when he said in *Geology of Canada*, 1863, page 896: "Two divisions have already been indicated in the stratified clays of Western Ontario, the lower of which was partially worn away before the deposition of the upper division, so that this rests unconformably upon it, adapting itself to the irregularities of the denuded surface. The latter is sometimes associated with beds of sand or gravel, a layer of which belonging to the upper division sometimes marks the contact with the underlying deposit. The upper division of these deposits, which is well exposed along the Saugeen River, may be called the Saugeen clay." On the other hand, as late as 1907-8, Messrs. Fritz Cirkel and J. J. Bell, reporting on Ontario for the Department of Mines at Ottawa, state in the *Mining and Metallurgical Industries of Canada*, page 749, in describing clay deposits at Casselman: "This yard contains about 10 acres of clay, with an unlimited supply on adjoining properties, blue below, red above, with a layer of sand on top. The sand and red-clay (Saugeen) are mixed for red brick. The blue clay (Leda) is too strong for brick making." Again in describing Mr. Pilon's yard—on the same page, they write: "There is an unlimited supply of clay which is formed in alternate layers of red and white (Saugeen), with sand between, in all about 12 feet, with blue clay (Leda) below." In view of these statements and my own confirmation from personal observation throughout Ontario, I still maintain that the Saugeen is a very characteristic and distinct clay, and the retention of the name Saugeen is not only useful, but desirable. I would

suggest that possibly Dr. Coleman has not distinguished between this characteristically laminated Saugeen clay and the weathered top of the Erie clay, which I have named Red Top. There is no possible confusion of these two clays.

My statement that the Leda clay in the East is contemporaneous in age with the Erie clay in the West, I admit is incorrect. My idea was that the Leda clay was contemporaneous with the later deposits of Erie clay, and I drew this inference from the concluding paragraphs of Dr. Coleman's valuable paper on Iroquois Lake—B. of M. Report, 1904. In his conclusions on page 243 we find the following: "The succession of events in the retreat of the last ice-sheet may be summed up as follows: (1) Retreat of the ice-front to the Oak ridges moraine set free the basin of Lake Ontario and drained off Lake Warren; but the St. Lawrence Valley from Havelock to Watertown, in New York State, was still blocked with ice so that the overflow from Lake Algonquin, occupying the basins of the three upper lakes, was impounded as Lake Iroquois which had an outlet past Rome, N.Y., into the Hudson."

(4) The partial or total disappearance of the ice dam left the St. Lawrence channel 330 feet or more lower than at present, and at a level with the sea, but the influx of fresh water from the upper lakes, and the narrowness of the strait near Brockville, kept the water fresh, so that marine animals went no further west than Brockville."

"As the ice abandoned the region of the Ottawa and St. Lawrence Valleys, and the low land lying between, the sea followed up its edge, etc. Though the water of the Ontario basin stood at sea level, it was apparently kept fresh by the rivers which flowed into it, especially Niagara."

From these paragraphs, as conclusions to Dr. Coleman's report, I inferred that fresh water Erie clay was still depositing in Iroquois and Algonquin Lakes, while marine Leda clay was depositing in the salt waters east of Brockville, and it was in this sense that I considered these two clays contemporaneous.

Yours truly,  
M. B. BAKER.

Geol. Dept., School of Mining, Kingston.

The Editor the Canadian Mining Journal:

Dear Sir,—In your issue of February 15th you published an interesting article by R. E. and A. R. Chambers, entitled, "Sinking of Wabana Submarine Slopes," splendidly illustrated and very interesting from a practical standpoint.

In this connection, however, I would like to discuss the paragraph on page 113 entitled "Testing Air Pipes." The paragraph is as follows: "All pipe ends are carefully closed as near to the drills as possible. A pressure gauge is connected to the section to be tested. The section is then filled from the mains and the supply valve closed. The air in the line is then released until the gauge reads 50 lbs. The time is taken and the pressure allowed to drop by leakage until it reaches 40 lbs. when the time is taken. The loss in cubic feet of free air will be approximately half the volume of the pipe tested. This divided by the time will give the loss per minute."

It seems to me that if the same procedure were carried through and the pressure allowed to drop to 42.65 lbs. the result would have been more accurate, since  $50 - 42.65 = 7.35$  lbs. = half the atmospheric pres-

sure. In other words, by allowing the pressure to drop  $\frac{1}{2}$  the atmospheric pressure, the amount or volume of free air lost by leakage would be half the volume of the pipe tested.

Why then should the pressure be allowed to drop  $10 - 7.35$   
to 40 lbs. entailing an apparent error of  $\frac{7.35}{10 - 7.35} \times 100 =$

36.05%, which seems hardly approximate as stated, especially when it is just as convenient to allow the pressure to drop to 42.65 lbs.?

Yours sincerely,

GERALD DOBBS.

Box 97, Bessemer, Alabama, U.S.A.

To the Editor of Canadian Mining Journal.

Dear Sir,—My attention was called to a letter in your issue of April 1st by "Reader."

This is a criticism of an article of mine in the mining Journal, London, of February 6th.

For your correspondent's information I might say the first article "Impressions of Cobalt," appeared in the issue of January 23rd. This was the first of a series, written at intervals, two of which have been published, the third, after five months' observation, is now with the publishers. These observations being continuous from October last to date, possibly now justify an "opinion"—formerly merely "impressions" were needed.

I fail to perceive what is the particular object of your correspondent's criticism or why, if the article in question appeared in the London Mining Journal, a criticism in the Canadian Journal would either be intelligible to the majority of your readers or fair to the writer.

It is regrettable that the last clause should have been indulged in, as reputable mining men do not so characterize technical writing however such differs from their own opinion.

It would have shown better taste had your correspondent signed his name. Personal criticism under an assumed name is not in accord with professional etiquette.

Yours truly,

H. E. WEST.

Cobalt, April, 1909.

April 3rd, 1909.

The Canadian Mining Journal,  
Confederation Life Building,  
Toronto, Ont.

Gentlemen,—In your issue of March 15th, page 186, you have a small paragraph regarding the Quaker City-Cobalt Mines, Limited, in which you state that there are a force of twenty men at work. The number of men at work should read seven instead of twenty. We appreciate your kindness in inserting the reading notice but as we are very desirous of having only facts appear in print, or elsewhere, we take the liberty of calling your attention to the error.

Again thanking you for the notice, we beg to remain,

Very truly yours,

Quaker City-Cobalt Mines, Limited,

Per J. M. Ford,

Vice-President and General Manager.

Haileybury, Ont.

## INDUSTRIAL PAGE.

**THE JEFFREY CRAB LOCOMOTIVE.**

The Jeffrey Manufacturing Company, Columbus, Ohio, has recently added to its line of electric mine-locomotives a new type of gatherer, known as the Jeffrey Crab locomotive. The gathering locomotive commonly used is provided with a reel of flexible insulated conductor, which enables it to enter rooms for the purpose of delivering empty mine-cars; to the work-

There are several methods of operating this locomotive to advantage, choice depending upon the system of mining followed where the locomotive is used. With the double-entry system, the locomotive usually hauls a trip of empty cars into one entry and drops them off where they are required. Returning on the other entry, it stops in front of each room where a loaded car is ready. The trip-rider then drags the cable into the

Jeffrey Crab Locomotive pulling car from room.

ing place and for hauling out the loaded cars. When the rooms are driven to the dip on steep grades, however, it is difficult for a locomotive which has to enter the room to work efficiently against the grade. When tracks are practically level and the cars not heavy it is found economical to push empty cars into rooms by hand, so that mechanical means are required only for hauling out loaded cars.

The advantages of employing a locomotive capable

room, attaches it to the car and signals the motorman, who starts the crab motor and pulls the car out to the entry track. The locomotive then either pulls it to the next room or leaves it standing until as many cars have been drawn from the rooms as are required to make up a trip. Then it pushes them together, and they are coupled up and hauled to the partings. On the return trip the empty cars are distributed in the entry from which the loads have been removed, and the locomotive

Jeffrey 5-ton Crab Locomotive, showing Crab device on which the haulage cable is wound.

of pulling out loaded cars without entering the rooms prompted the Jeffrey Manufacturing Company to bring out this crab locomotive, which was so named from a small winding drum, or crab, which is mounted on the forward end of the locomotive. Three hundred and fifty feet of  $\frac{3}{8}$ " flexible wire-cable wound on this crab is used for pulling the loaded cars from the rooms and to the entry tracks.

gathers the loaded cars from the entry which was supplied with empties on the preceding trip.

Where the single entry system is employed, the locomotive usually runs in with a train of empties. Stopping successively in front of the rooms in which loaded cars are ready, it hauls each car to the entry-track and pushed it ahead to the next room, dropping off an empty to replace each loaded car taken on. When all empties

have been distributed it proceeds to the parting with the loads gathered. By each of these methods a locomotive can gather from 75 to 200 cars per day, depending upon local conditions.

The crab device is made as compact as possible to avoid crowding the rest of the locomotive equipment. It consists of a cast-iron drum upon which a steel cable is wound. This is mounted on a vertical axis contained in a frame, the top of which supports the motor, which is connected by suitable gearing and a friction-clutch to the drum. The motor drives this gearing through a worm and worm-wheels, so that when it stops the gearing is locked against further motion. The drum is driven by the gearing by a friction-clutch, which acts not only as a smooth starting device for the cars, but also as a safety device in case a car becomes derailed or the motorman fails to throw off power until the car bumpers strike those of the locomotive. Without this friction arrangement the cable would break, in such cases or serious injury result to the gearing or to the motor itself.

The motor which actuates the crab, being entirely separate from the locomotive motors, is controlled by a separate starting box, and when the car approaches the entry tracks the motorman starts the locomotive ahead. As it advances past the switch points the car follows, and runs out upon the entry tracks without either the locomotive or the winding of the crab being stopped.

The crab may be stopped when the car strikes the locomotive; but the locomotive need not stop until the room is reached from which the next load is to be hauled. Then the trip-rider uncouples the cable and drags it into that room for the car. The arrangement is such that the cable may be paid out from either end of the locomotive. Ordinarily, it is more convenient to take the cable out past the motorman, as the end of the locomotive is then opposite the room-mouth and the motorman can watch the light carried by the trip-rider and see him signal to start winding. He can also watch the car to better advantage as it takes the switch, and can step instantly if it should become derailed. One great advantage claimed for the crab locomotive is that, it may replace animal haulage without making changes in the tracks or conditions in the working rooms of the mine.

At recent tests on concentration made by the Behrend Concentrators, Limited, at its plant, 48 Inspector St., Montreal, remarkable results were obtained from ores generally known as difficult concentrating ores.

On a run of chalcopryite from the Massey Mines, a saving of over 95% was made.

On 3% graphite, over 90%.

On 20% graphite, a saving of 92%.

On Cobalt slimes, over 97%.

The Behrend system is composed of the dry table for meshes from 10 to 80, and from 80 to and including slimes, a wet system is used. The dry fines are fed on moving water, the gangue and granulated mineral sinking, while the float mineral is carried to a filtering tank. The gangue and granulations are drawn off by spigots and fed to the head of a wet table, 6 inches wide by 12 feet long. This table is a sluice box containing six separate concentrating tables, the mineral bedding on each table and is continually drawn off. At the foot of each table or compartment, is placed a ducker, thus giving all solid matter a thorough wetting before it reaches the next table.

#### Concentration of Lead, Zinc, Copper, Tin and Iron Ores.

Bulletin No. 1437, January 1909. Allis-Chalmers Company, Milwaukee, Wis., U.S.A.

The catalogues of this firm are always of interest. Opening with a few general notes of definition this bulletin then covers the field of mechanical equipment for concentration, grizzlies, breakers, rolls, elevators, screens, jigs, separators and classifiers, pulp extractors, Huntington and Chilian mills, Overstrom tables, suspended and Frue vanners, spiral sand pumps, are taken up in the order given. To make the pamphlet logically complete two flows sheets of concentrating plants are appended.

The Brown Machine Co., Ltd., of New Glasgow, N.S. has been incorporated with a capital of \$100,000. This concern are manufacturers of mining and other machinery and dealers in mining supplies. It is their intention to build new and larger shops and to increase their output of coal mining equipment.

Recently orders for Analytical balances with the Ainsworth Improved Multiple Rider Carrier have been received by Wm. Ainsworth & Sons, Denver, Colorado, U.S.A., from the United States Food Inspection Laboratory, Denver, Colo.; the United States Mint, San Francisco, Calif., and the Watertown Arsenal, Watertown, Mass.

## NEW MINING AND METALLURGICAL PATENTS.

### No. 115,344. Rock Drill.

The Ingersoll-Rand Company, New York City, assignee of William Prellwitz, Easton, Pennsylvania, U.S.A., 1st December, 1908; 6 years. Filed 29th June, 1908. Receipt No. 160,204.

Claim.—1. A cylinder, a front head, a hollow drill steel, a water feed chamber, a separate air supply chamber, and reciprocating drill piston having a duct therein arranged to be brought alternately into communication with the water feed chamber and the air supply chamber for feeding water and air alternately to the drill steel.

2..A cylinder, its piston chamber, a front head, a water feed chamber therein, a hollow drill steel and a reciprocating drill piston, having a duct therein arranged to be brought alternately into communication with the water feed chamber and the piston chamber for feeding water and air alternately to the drill steel.

3. A cylinder, its piston chamber, a front head, a sleeve therein having inner and outer connected annular spaces forming a water feed chamber, a hollow drill steel and a reciprocating drill piston having a duct therein arranged to be brought alternately into communication with the water feed chamber and piston

chamber for feeding water and air alternately to the drill steel.

4. A cylinder, its piston chamber, a front head, a sleeve therein having a water feed chamber, a hollow drill steel, a reciprocating drill piston having a duct therein arranged to be brought alternately into communication with the water feed chamber and piston chamber for feeding water and air alternately to the drill steel, a packing for the piston rod at the inner end of the sleeve and a packing for the piston rod and sleeve at the outer end of the sleeve.

5. A hollow drill steel, a piston rod having a duct therein communicating with the bore of the drill steel, a chuck for receiving the drill steel, a bushing and a gasket at the inner end of the bushing, arranged to en-

circle the end of the drill steel for forming a water tight joint at the drill steel seat, the opening in the chuck for the gasket being of less diameter than the opening for the bushing, thus forming a shoulder against which the inner end of the bushing seats.

6. A hollow drill steel, a piston rod having a duct therein communicating with the bore of the drill steel, a chuck for receiving the drill steel and a gasket located at the drill steel seat arranged to encircle the end of the drill steel to form a water tight joint, the said chuck having a transverse hole leading to the gasket for facilitating its removal from the chuck.

7. A hollow drill steel, a piston rod having a duct therein communicating with the bore of the drill steel, a chuck for receiving the drill steel, a bushing and a gasket located at the inner end of the bushing in position to encircle the end of the drill steel at its seat, said chuck having a transverse hole leading to the gasket for facilitating the removal of the gasket from the chuck.

#### No. 115,611. Explosive.

Wesley Oliver and Alfred Stephens, co-inventors, both of Gelert, Ontario, Canada, 15th November, 1908; 6 years. Filed 10th September, 1908. Receipt No. 162,322.

Claim.—An explosive comprising charcoal, sulphur and chlorate of potash, substantially in the proportions set forth.

#### No. 115,362. Electric Apparatus for the Ignition of Mines.

Otto R. B. Berglund, Walter Axel, W. E. Hyorth and Carl E. Spungman, co-inventors, all of Stockholm, Sweden, 1st December, 1908; 6 years. Filed 8th August, 1908. Receipt No. 161,435.

Claim.—In an electric mine igniting apparatus the combination with a magneto and a mine exploding cir-

cuit, a transformer having primary and secondary coils, a pair of spring contacts connected one with the primary coil of the transformer, and the other with the mine circuit, a contact post located between said spring contacts and connected with the secondary coil of the

transformer, said spring contacts tending normally to bear on said contact post and a switch lever electrically connected with the magneto and adapted to contact with one of the other of said springs and on said contact to move it out of contact with the post, and means whereby the lever is operated by the magneto.

#### No. 115,510. Igniter for Blasting Fuses.

Benjamin F. Pearson, Canyonville, Oregon, U.S.A. 8th December, 1908; 6 years. Filed 22nd June, 1908. Receipt No. 159,993.

Claim.—1. A fuse protector and igniter comprising a metal cap having a reduced or contracted outer end and adapted to be applied to the outer end of the fuse, and means in the outer end of said cap whereby the fuse may be quickly ignited, substantially as described.

2. A fuse igniting device comprising a cap or ferrule having a reduced or contracted open outer end, and a wad of highly inflammable material packed in said outer end, substantially as described.

3. An igniting and protecting device for blasting fuses, comprising a ferrule or cap adapted to be applied to the outer end of a fuse, said cap or ferrule having a contracted or inwardly turned open outer end, an igniting wad arranged in said outer end of the ferrule, said wad consisting of a composition of raw cotton, and powder adapted to be packed or rammed into the outer end of the cap, substantially as described.

4. An igniting material for fuses consisting of a composition of raw cotton, gun powder and giant powder constructed in the form of wads, and means to hold said wads in engagement with the end of the fuse, substantially as described.

5. A fuse igniter consisting of raw cotton mixed with gun powder having combined therewith a small percentage of giant powder, such gun powder and giant powder being mixed with water to form a pasty solution which is thoroughly mixed with the cotton and formed into small rolls and dried, after which said rolls are cut into lengths or pieces to form igniting wads, and means whereby said wads are held in engagement with the end of the fuse, substantially as described.

6. A fuse igniter consisting of raw cotton mixed with gun powder having combined therewith a small percentage of giant powder, such gun powder and giant powder being mixed with water to form a pasty solution which is thoroughly mixed with the cotton and formed into small rolls and dried, after which said rolls are cut into lengths or pieces to form igniting wads, and a metallic cap or ferrule adapted to be applied to the end of a fuse to hold said igniting wad in engagement therewith, substantially as described.

## SPECIAL CORRESPONDENCE

### ONTARIO.

**Cobalt.**—The rush of freight from Charlton to Gowganda is greatest about the middle of March, about eight hundred teams being employed. The road from Charlton to Elk Lake is in fair shape, but between the latter place and Gowganda it is very bad. Apparently very little attempt was made to get a good grade, which was an easy thing to obtain, and where it was a question of going over a steep hill, or making the road a mile longer by going round, the contractor struck out for the high places. As a consequence, it takes a good team to pull 500 pounds, and as teams are worth from \$350 to \$600, it can be seen that drawing freight is an expensive item. A great many pitch-holes are encountered and spills are an everyday occurrence. During the third week in March 500 loaded teams left Charlton in one day.

On April 2nd there remained at Charlton only twenty cars of supplies, and these, with five en route, completes the total billed for Gowganda.

Although there are undoubtedly many good properties in Gowganda, the general consensus of opinion seems to be that the district has been grossly misrepresented by some of the papers. This will do much harm, and when the snow leaves the ground the district is undoubtedly due for a bad black eye.

The Bartlett Company were unable to take in their two 80 horsepower boilers, which are now across the lake from the camp. As soon as the ice breaks up sufficiently they will be floated across.

The Gowganda Queen Mining Company has a force of fifteen men at work sinking a shaft on their property west of the Mann claim. The shaft is being sunk on a three-inch vein of calcite carrying silver values.

The new compressor plant of the Moose Horn Mining Company, at Elk Lake, has arrived on the property, and everything is in readiness to install it in a short time. It consists of a 100

horsepower boiler, a three-drill compressor and a hoist. A shaft is now down 60 feet, but as soon as the new plant is in operation, it will be sunk to a greater depth, as the management finds that profitable mining cannot be done on the small veins encountered on the present levels.

Twenty men are employed on the property of the Montrose Syndicate, in South Lorraine, erecting buildings for the steam plant which will shortly be installed. The shaft is now down over thirty feet on a vein carrying cobalt and nickel, but no silver. Sinking will be continued to the 100-foot level before any drifting is done.

Plans and estimates have been prepared for the erection of a suction gas producer plant at Dane, in Boston Township, for the purpose of supplying power to a number of mines in the Larder Lake district. The cost would be in the neighborhood of \$100,000.

Another company has been formed to develop a waterfall, for supplying power to the mines in the Cobalt district. The falls are on the Matabichehewan River, near the mouth of the Montreal River, and it is estimated that 10,000 horsepower can be developed. Surveys have now been under way for several weeks.

A new company called the Paymaster Mines, Ltd., with a capital of \$2,000,000, has been formed by Mr. S. D. Madden. They will probably buy the property of the Cobalt Treasury Mining Company, and with it twenty other claims in Coleman.

The Canadian Copper Company have taken a working option on the big pyrrhotite deposit near Driftwood City. Four diamond drills are being taken in to test the deposit at depth. The option is for \$250,000.

The Drummond mine is said to be under option to Leivishon, of New York, who is heavily interested in Kerr Lake. Negotiations are still under way, as the price has not definitely been settled on.

The Verner Silver Mining Company, owning two claims in the Matabichehewan district, have been doing development work

during the winter on veins discovered by trenching. Shaft has been sunk on one of the veins, for a depth of twenty feet, and will be continued to the 75-foot level. Camps have been erected and the company may install machinery in the spring.

A force of thirty men are at work on the claims of the Langham Mining Company, in James Township. The shaft is now down over fifteen feet, and will be continued to the 100-foot level before any drifting is done. A calcite vein is showing in the shaft.

Good progress is being made at the Chambers-Ferland, and the company expects to ship five cars of ore in April. A sixty-foot crosscut will be run from the 100-foot level of the No. 1 shaft, to cut the rich vein which has been worked on the La Rose. A drift will be started from the No. 60 shaft of the Nipissing Mining Company to develop the Chambers-Ferland ground. This shaft has been leased from the Nipissing. The crosscut being run by the Right of Way to tap the veins under the compressor building, will soon be in the required distance.

The Lumsden, mine located out near the Temiskaming, is putting in a small steam plant, consisting of a 20-h.p. boiler and a 6x8 hoist. This temporary plant will be used to sink the shaft to the 150-foot level.

The contract which called for the sinking of a 125-foot shaft, on the Hylands property in Coleman, has been completed. A station has been cut at the lower level, and a drift started on the vein, which shows up well in the shaft.

A diamond drill is doing prospecting work at the Badger mine, and one hole, having a vertical depth of 250 feet, was put down under the swamp. It failed to locate any veins. A force of men are at work repairing the timbers in the shaft, and putting the buildings in condition.

The new vein, found about two weeks ago at the Cobalt Lake, is being drifted on, and continues to show good values. Reports have been circulated that No. 6 shaft was flooded by water from the lake, but these reports are without foundation.

The Crown Reserve has made a find in the shape of a 2-inch vein, carrying high silver values, found in the north crosscut being run east under Kerr Lake. Another new vein was discovered in the east crosscut at the 100-foot level. The shaft sunk from the open cut is now down over 165 feet, and will be continued to the 200-foot level.

At the Floyd the shaft is now down over two hundred feet, but as the vein is badly broken up in the bottom, sinking will be discontinued.

The west drift from the No. 4 shaft of the Cobalt Lake Mining Company, which has been leased to the Cobalt Station Grounds Company, is now within a short distance of the latter company's boundary. In the north Lake shaft the drift is also very close to the line. A force of twelve men are employed.

At the 100-foot level of the winze, sunk from the tunnel of the Mother Lode mine, a crosscut to the west tapped the vein on which the tunnel was originally driven. The ore shows good values at this depth, which is about 240 feet from the surface.

A new vein, showing values in native silver, has been located on the surface at the Kerr Lake Majestic, about 120 feet north of the main shaft. The main shaft is down over 45 feet on the vein, but it will be continued to the 125-foot level before any drifting is done. Another shaft is to be sunk to a depth of 100 feet, with the expectation of striking some of the Drummond and Kerr Lake veins. A force of thirty men are at work on the property.

The plant of the Ophir mine, consisting of a 100-h.p. boiler, a seven-drill compressor, and a 6x8 hoist, has been installed.

The Temiskaming mine has made an important strike on the Ganz lot, the vein being about 10 inches wide and carrying high grade silver values. The mine is in excellent condition, the de-

velopment work being kept well ahead of the stoping. The ore on the 250-foot level is proving richer as the drift is driven to the vein.

The plant of the Red Jacket is now on the ground and the company expect to turn on the air about April 15th.

The Michigan Cobalt Silver Mining Company, owning properties south of the Farrah, are starting to sink a shaft. The hoist is run by a 25-h.p. boiler, and air for one drill is being obtained from the Kerr Lake Majestic. The shaft is being sunk away from the vein, and at the 100-foot level a crosscut will be run to tap it. The vein was discovered by surface prospecting last fall, and is about five inches in width.

The new plant of the Consolidated Mines Company is now in operation. Two drills are being employed sinking on the Green Meehan, while a 3-inch line has been laid to Red Rock, to supply air when the management decides to commence work.

The Silver Tunnel Mining Company, adjoining the Otis Curry on the north, has discovered a new 3-inch vein carrying silver values. This makes a total of six new veins found this year. A tunnel 200 feet long will be driven on one of the veins and crosscuts will be driven from the face. A small plant consisting of a 40-h.p. boiler, and two drills will shortly be installed.

The Crown Jewel Mines Company have received permission from the Government to increase their capitalization from \$350,000 to \$1,000,000.

It is reported that one of the two diamond drills working at the Silver Queen has located a new 6-inch vein of high grade ore.

The directors of the Muggley Concentrator have decided to make additions to the mill that will increase the capacity to about 120 tons a day.

Operations have been suspended in the underground working of the Peterson mine, and prospecting is being carried on by means of diamond drills. One hole has been started from the surface and when that is completed, the drill will be moved to the bottom of the shaft, and horizontal holes bored to test the surrounding country.

A diamond drill is being used to prospect the Gamey property, now owned by the Cobalt Central.

The plant of the Blackburn mine, Miller Lake district, is now on the ground, and is being installed. It consists of three 50-h.p. boilers, two 3-drill compressors and 2 hoists. The power will be generated in one central station and lines to carry the air will be laid to the separate workings.

On April 2nd a 4-inch vein was found at a depth of 75 feet in the crosscut to the west of the main shaft of the Gold Consolidated Mining Co. at Cart Lake.

The Casey Cobalt Mining Company, operating north of New Liskeard, have sunk a 260-foot incline shaft on a cobalt vein. At the 220-foot level a station has been cut and drifts started in both directions. The company has staked sixteen other claims in the vicinity of their property. A small shipment of cobalt ore will probably be made in April.

Good progress is being made by the Brydgette Syndicate, operating 20 acres in the northwest corner of Peterson Lake. The new plant, consisting of a 125-h.p. boiler, a six-drill compressor and a hoist, is now ready, and all the buildings are completed. The shaft, which is down 50 feet, will be continued to the 150-foot level, at which depth crosscuts will be run to prospect the surrounding country, and to tap the veins that have been located by surface prospecting.

On the Peterson Lake lease of the Little Nip, at the 150-foot level, a good pay chute has been located on a vein in which considerable development work had previously failed to show silver values. Another vein, 4 to 6 inches wide, was also found on the 200-foot level. The ore is high grade, and the wall rock for a foot on each side is well mineralized.

The Montreal Reduction Company, at Trout Mills, is putting in furnaces to treat the high grade ore from this district, and when these are in operation the company expects to be able to treat the ores, at a lower charge than Denver or Perth Amboy.

The Nipissing Reduction Company's mill has been undergoing extensive alterations for the past month, but the company expects to have things in running order again by April 15th. The mill was originally designed as a dry concentrator, but this method proved to be a dismal failure. The concentrating machines were then thrown out and wet tables installed, while the crushing end remained dry. Although satisfactory results were obtained the company realized that more economical results could be obtained if the plant were running entirely on the wet process, so the necessary changes were made. The crushing end consists of two 6x20 jaw crushers, six sets of rolls, and a Hardinge mill. The concentrating end consists of four double compartment Hartz jigs, two Wilfley tables, seven James tables, and a James slimer. The capacity will be 80 tons a day.

### BRITISH COLUMBIA.

**Boundary.**—About a week ago the British Columbia Copper Co. posted a notice at their works that they would cease operations about April 1st but it has now transpired that such will not be the case and that the mines and smelter will be kept going unless copper drops to a much lower price than is prevailing at present. It is stated that the Greenwood miners' union upon hearing that it was likely the company would stop work voluntarily offered to accept a reduction of 10 per cent. in wages and the Copper Co. informed the miners that if such an arrangement was made it would reduce the price of board and supplies 10 per cent. to correspond. The B. C. Copper Co. has paid the first installment of \$10,000 on the bond of the properties recently acquired in Wellington camp. The purchase price was about \$100,000. The mines are showing up well and there is a large quantity of good ore on the dumps ready for shipment as soon as the new railway spur is built in.

The Greenwood city council seems favorably inclined to the tunnel scheme proposed and has passed a by-law bonusing the project for about \$50,000—\$15,000 to be paid when the tunnel is in 3,000 feet, a similar amount when the adit has been driven 6,000 feet and the balance when the work is advanced to Phoenix camp. This by-law will be put to a vote of the people and if that is favorable it is likely that work will be started immediately.

Work will soon be resumed at the mill and Nickel Plate mine of the Daly Reduction Co., at Hedley. Mill Superintendent Holbrook and Mine Superintendent Jones are in their places organizing their working forces and getting the flume and other surface appliances in form for an early resumption of operations.

A force of men is working on development at the mines of the Donald Copper Co., three miles west of Midway. Eighteen men are working at the Golden Eagle Mine, Volcanic Mountain. Six cars of ore averaging \$23 per ton were shipped last week and for the near future about a car a day will be sent out regularly.

Mining has again been resumed at the Snowshoe Mine of the Consolidated Co. Shipping has been going on regularly but the ore was being taken from the reserves which have been cut down considerably, making it advisable to start stoping again. The tunnel on the Phoenix-Amalgamated group of this same company is nearly complete. A goodly tonnage of ore has been placed in the stoping area by the development work done during the past few months. The next progressive step in the plan of this property will be building the railway spur into the property to afford economical shipping facilities.

A small mill is being built on the West Fork of Kettle River to treat the second class ore of the high-grade mines near

Beaverdell. An experimental mill is also being built at the Jewell Mine. This is a slimes process the invention of H. Nicholls of the Ymir Mine.

A 5-foot vein of good coal has been uncovered about three miles west of Midway, B.C. The presence of this vein has been known of for some time and the formation thereabouts is favorable but this is the largest vein located so far.

**Rosslund.**—The rich ore shoot on the 90 level of the War Eagle Mine is opening up in good quantity and the ore is maintaining its quality. Work in other parts of the group of the Consolidated Co. is giving good results and the prospects are fine for a big tonnage and substantial profits this year.

With the advent of spring the miners are beginning to look up properties to lease and there are several parties after the Evening Star and other likely mines. A few small pockets of ore carrying coarse free gold have been opened up in the I.X.L. Mine by the lessees and work is being pushed vigorously in the hopes of soon encountering one of the bonanza pockets. The mill is being repaired at the O. K. and mining and milling operations will soon be resumed on that property by the lessees.

There is nothing new in Le Roi affairs and there is not likely to be much of consequence done until Mr. McMillan has started raising funds in London. The Northport smelter, which has been treating a small tonnage from the Sheep Creek, Ymir and adjacent British Columbia mines and also a tonnage from small mines along the Great Northern in Washington, as well as the Le Roi ore, will shut down indefinitely in a few days, or just as soon as the work of cleaning up can be completed.

The old War Eagle, Centre Star and St. Eugene mining companies, which were taken over by the Consolidated Mining & Smelting Co. of Canada, are being wound up by C. R. Hamilton, liquidator, Rosslund, B.C.

The fiscal year ending September 30th, 1908, was the best one financially that the Le Roi 2, Limited, has so far had in the history of its work in this camp. The annual report shows a balance in favor of profit and loss of £53,053 2s. 6d. During this period the company shipped 29,648 tons of ore of an average value of \$23.60. The mining cost including depreciation, was \$5.31 per ton; smelting and freight charges were \$5.55.

**Nelson District.**—The news that the coal miners of the Crow's Nest and Alberta districts had decided to strike was received here with some apprehension, even though it is said that the Crow's Nest Pass Coal Co. will continue to work. It is thought that the leaders and officials have misled the men as is too often the case in affairs of this kind.

The Second Relief mine at Erie has been bonded by A. B. Cooper, President of that Company, to Wisconsin mining men, who are represented in the deal by R. W. Allen.

Work will soon be resumed on the Eva gold mine at Camborne. The property is on the market as being for sale, but the owners have nevertheless provided funds with which to get to work.

A number of the smaller properties have appeared on the shipping list lately among them being the Bismark, 255 tons; Yankee Girl, 94; Mother Lode, 48; Hope, 8; Fisher Maiden, 78; Ruth, 145; Emerald, 623, etc.

Work has again been started on the old Payne mine. A plan of diamond drill exploration will be carried out in an effort to find the continuation of known and rich shoots of ore in the workings.

Thirty men are working on the Standard property at Silverton. This group comprises ten claims from which over 245 tons of ore have already been shipped this year. This ore is valued at about \$35 per ton or over \$750 per car.

D. C. Corbin, the Spokane railway magnate, has bonded the Wagner group of claims on the Upper Duncan River. This group

is valued at nearly one million dollars. It is anticipated that Mr. Corbin will have enough influence with the "powers that be" to get that long looked for railway line built up the Duncan, in which case the many rich mines in that locality will be afforded facilities that will enable them to be worked and ship at a profit.

The long tunnel at the Hosmer mine has now been driven over 4,100 ft. and so far but eight of the fourteen known coal veins have been pierced. It may be found necessary to drive this adit 8,000 feet altogether. There are 80 coke ovens now in commission at Hosmer, about one-third of what the first installation will amount to.

## GENERAL MINING NEWS.

### NOVA SCOTIA.

**Port Morien.**—The output of the North Atlantic Colliery Co. is now 400 tons daily. Satisfactory progress is being made in development work, and it is expected that the output will reach 500 tons by the time navigation opens.

**Sydney.**—The Marsh Mine, of the Nova Scotia Steel & Coal Co. is to be shut down indefinitely on March 31st.

### ONTARIO.

**Seaforth.**—A well has recently been sunk one mile southwest of Beachville, Oxford County, for the Standard White Lime Co. It was drilled with the expectation of striking gas, but although all formations from corniferous limestone to Laurentian granite were penetrated no gas was encountered. At a depth of 150 feet a flow of 150 gal. per minute of potable water, slightly sulphurous, was obtained. Salt water was met with at 665 feet. The total depth reached was 2,789 feet, or 1,896 feet below sea level.

**Maple Mountain.**—The shaft on the property of the Canadian Ores Co. is down 120 feet, and will be driven to the 150-foot level before another station is cut. At the 75-foot level a crosscut was run 40 feet northeast and caught the main vein. Where caught the vein ran from three and a half to six inches in width of calcite, smaltite and silver. A large plant is at present being installed consisting of a ten-drill compressor, two 100 horse power boilers, a large hoist with pumps, etc. The plant will be running in a short time.

**Cobalt.**—Very little underground work is being done at the Badger Mine, the main work being confined to the timbering and straightening of their main shaft. This shaft is down 225 feet and some drifting has been done at that level. A large cage has been ordered and shipped for hauling muck from the various levels of No. 9 shaft. At present 55 men are employed.

From the 200-foot level of the Rochester the crosscut to the east has been driven thirty-four feet, but the vein, which they expected to catch thirty feet from the shaft has not yet been located. A force of fifteen men are employed under Mr. C. E. Beard.

The Right of Way Mining Co. have opened up a new vein in the winze below the first level of No. 3 vein, which will probably carry over into Princess ground. It is 5,000 ounce ore and is about 6 inches to 8 inches wide.

The Kerry Mining Company have run across a vein on their Cart Lake lease, carrying silver at the 100-foot level. The vein was struck 120 feet from their shaft, and is four inches wide of calcite with silver. On the other lease held by the company situated on Peterson Lake, the workings are down over 125 feet. Forty men are employed on the property.

An 18-inch vein assaying 5,000 ounces was struck recently in the north drift at the 250-foot level of the Temiskaming.

**Vancouver.**—The Granby Consolidated Mining, Smelting and Power Co., of Grand Forks, B.C., has bonded a rich group of copper claims near Tassu Harbor, Moresby Island. One payment has been made on the purchase price, which is approximately \$100,000. A ledge on one of the properties there is 250 feet wide of chalcopryite, carrying 8 per cent. to 16 per cent copper, \$6 to \$14 gold and \$1.80 to \$2.20 silver.

Kamloops keeps active and on the strength of the mining situation considerable real estate is changing hands. The arrival of W. O. Young to take up the bonds he has on a number of properties, is looked forward to with some expectation. Work is going on at the Iron Mask, Kimberley and Copper King.

The Silver Cross Mine is installing a three-drill air compressor and a new boiler, and crosscutting will be resumed. The last shot put in the crosscut at the 20-foot level cut a good vein of calcite and smaltite.

The Pontiac Mine is now down 70 feet and drifting towards the Silver Cross line, which is between 200 and 300 feet away. The Pontiac will rent air for one drill from the Silver Cross.

At the Trethewey vein G has been sunk 230 feet, and three levels have been worked. On the third level a drift has been run 160 feet until it lies under No. 2 shaft. Vein H has been worked for 600 feet east and west on the 150-foot level. On the second level of No. 1 shaft a drift is being run east on E vein. The drift is 170 feet and the vein averages four inches of cobalt carrying some silver. A crosscut 650 feet in length connects this shaft with No. 2.

A sample of the Silver Cross dump from September 2nd, was shipped to the Behrend Concentrators, Ltd., at Montreal, for concentration, with the result that the dump produce was brought up to a valuation of \$400 from low values.

The main shaft of the Temiskaming and Hudson Bay Mining Company is down a depth of 200 feet, with stations cut at each fifty feet. The drift in the main vein has now been driven nearly 200 feet to the east, the vein showing an average width of eight inches of smaltite and native silver. A crosscut is being driven to catch their No. 3 vein and the Trethewey vein.

The Canadian Copper Co., of Copper Cliff, have taken an option on a group of claims near Driftwood City on the T. & N. O. They are placing four diamond drills to test the deposits, which are of nickel, to a great depth.

**Elk Lake.**—Nearly twenty-five companies, including properties around Elk, Silver, Miller and Gowganda Lakes, have installed or ordered machinery to work their claims.

The Principal installations in the Gowganda Lake district include: The Bartlett Mines, with a 12-drill compressor, boilers, hoists, pumps, drills, etc.; the Boyd-Gordon, with a 6-drill compressor, etc.; Reeves-Dobie, with a four-drill compressor, etc.; and the Mann, which has installed two plants, each with a twenty horse power boiler to run the drills and hoists by steam.

Plants have been ordered for the Gates and Bonsall properties in the Miller Lake district.

The majority of the new plants will be in the vicinity of Elk Lake City and Silver Lake. Last winter the Moose Horn put in a steam plant run by a fifteen h.p. boiler, which has been replaced this winter by a three-drill compressor.

The first compressor plant in the district was the six-drill compressor installed by the Elk Lake discovery.

The Otisse Mine have an eight-drill compressor plant working and the Otisse-Currie are installing a plant of the same capacity.

The Gavin-Hamilton, Big Six, Copper Cliff, Hayden and Toledo Mines are all installing plants at the present time.

In Nos. 1 and 2 veins of the Elk Lake Discovery a shaft has been sunk for a distance of forty-two feet. The veins are calcareous, carrying niccolite and leaf silver. At the fifty-foot level a shaft will be cut and some drifting done, and then the shaft will be continued to a depth of 150 feet before any considerable underground development will be done.

A six-drill compressor, sixty-five horsepower boiler, and four drills are being installed at the Gavin-Hamilton. The shaft is now down fifty-seven feet, and drifting has been commenced.

A new strike is reported from the Otisse-Currie property. The new vein is 18 inches wide and has been traced for 200 feet. It is on another part of the property from which the present shaft is being sunk. The present shaft is now down 25 feet and will be sunk to the 100-foot level before crosscutting is started.

**Port Arthur.**—The West End Silver Mountain Mine, which has been closed down for the past year, is to be re-opened within a few days. The Porcupine, another property belonging to the same company, the Consolidated Mining Co., is to be re-opened also.

The news comes from the Sturgeon Lake region that the St. Anthony Reef Gold Mine will re-open shortly.

#### BRITISH COLUMBIA.

**Fernie.**—The Crow's Nest Pass Coal Co. has ten mines in operation, but only two are productive at present. By next October the production will probably be 6,000 tons, or, perhaps, 10,000 tons per day. The company have under consideration the building of 1,000 coke ovens.

The new agreement recommended by a joint conference of miners and operators at Macleod, Alta., was ratified by the Fernie miners by a majority of 250, and the district officials signed the agreement March 30th. It is for two years, and covers all mines except Nos. 1 and 9. It is practically the same as the former agreement, but it is claimed that the better working conditions provided will permit of a ten to fifteen per cent. advance in earnings.

**Rossland.**—Fire broke out in the 400-foot level of the Centre Mine on March 18th, about eighty feet from the shaft on the west stope. It was extinguished after a strenuous fight lasting about twenty hours.

A stamp mill is shortly to be erected at the Jewel Mine. The machinery has already arrived.

**Grand Forks.**—The Granby is operating seven of its eight furnaces, one being out of commission owing to its being enlarged to the size of No. 1 furnace. When this enlargement is completed No. 3 will be torn down and enlarged, as well as all the rest of the battery, one furnace being enlarged at a time. Fourteen per cent. of the men at the mines at Phoenix will be laid off during the enlargement process.

**Greenwood.**—The B.C. Copper Company announced that owing to the condition of the copper market, they would close

down their mines and smelter. Later, however, word was received from New York of a better outlook and work will continue as usual.

**Nelson.**—A three-foot pay-streak has been struck in the Summit Mine at Sheep Creek. It is typical sulphide ore, samples of which many prominent mining men say to be among the richest yet seen in British Columbia. The Summit shipped half a carload of ore two years ago, but since that time work has been confined to development. Shipments to Trail smelter will commence at once.

Thos. Kiddie, manager of the Northport smelter, has announced that that enterprise will close down owing to the shutting down of the Le Roi Mine at Rossland from lack of ore.

A gold brick weighing 465 ounces and valued at over \$7,000 has been brought in from the Nugget Mine at Sheep Creek. This is the result of about three weeks' work of the mill on ore mined from development work.

A. B. Cooper has bonded the Second Relief Mine at Erie to a Wisconsin Syndicate for \$140,000. The property is well developed and has a fine stamp mill.

The option on the Nugget Mine, which expired recently, has been renewed at a greatly increased figure, to the same parties.

**Vancouver.**—Extensive development will take place at the copper-gold camp at Tassoo Harbor, Moresby Island, this summer. The Granby Company recently acquired the O'Connor Group, and the Tyee Smelter has bonded the Harris Group. A group of twenty claims is owned by a syndicate composed of Messrs. A. Gowing, of Kootenay; F. C. Elliott and Hon. Thomas Taylor, of Revelstoke, and J. E. Corlett, of Seattle.

Mr. Justice Clement has issued an order for the sale of the Dominion Copper Company properties to satisfy the mortgage held by the National Trust Co., of Toronto, trustees for the bondholders. The order, however, only covers those properties acquired by the bond issues back of the mortgage.

**Nanaimo.**—The Vancouver Briquette Company intends to instal a plant in this city at a cost of \$30,000 or more, that will have a capacity of 100 tons per day.

The company has an agreement with the Vancouver-Nanaimo Coal Company for a supply of slack coal and has secured a site near Hoggan's Wharf.

#### YUKON.

**Dawson.**—A strike of from three to fifteen dollars to the pan has been made on Lower Glacier Creek, 80 miles west of Dawson. The new pay is on the protruding tip of the land lying between the forks of Glacier and Big Gold. The depth to bed rock is 16 feet, and the pay has been traced 300 feet up and down stream, 30 feet wide.

The Stewart River Dredging Company intend constructing two additional gold dredges this season for use on the Stewart River. The company had one dredge in operation last season, with very satisfactory results.

## MINING NEWS OF THE WORLD.

#### GREAT BRITAIN.

The output of coal last year was 261,506,379 tons, as against 261,812,852 tons in 1907, a decrease of 6,306,473 tons. The decrease in the output is at the rate of 2.35 per cent.

The number of persons employed under the Coal Mines Regulation Act was 987,813, of which number 796,329 were employed underground, the total the year previous being 940,618, showing an increase last year of 47,195.

The total output of minerals under the Metalliferous Mines Regulation Act during the year was 3,124,397 tons, against 3,338,024 tons in 1907. The chief item was 1,549,469 tons of

iron ore, against 1,802,946 tons in the preceding year. The number of persons employed was 29,927, against 31,602 in 1907.

Lord James of Hereford, the independent chairman, has given his casting vote in favor of a reduction of five per cent. in the wages paid in the Federation area in England and North Wales.

#### RUSSIA.

The Assistant Minister of Commerce has announced that a bill is to be submitted to the Douma fixing the responsibility for reckless exposure of lights in mines.

The Naptha works at Bibi Eibat have been burnt. Five of the Subaloff works, one of the Rothschild, two of the Schibaieff, and two of the Wotan Company's works have been burned down. Two Mahomedan peasants, suspected of incendiarism, have been arrested.

#### GERMANY.

The collapse of the Lorraine Luxemburg Pig-Iron Syndicate has now thrown the German pig-iron trade open to competition. The first effect of the dissolution has been a reduction of 2s. in the price of Luxemburg foundry iron.

The Krupp Company and the German Arms and Ammunition Company, of Berlin, are reported to have received from the chief of the Argentine Military Commission large orders for war material for Argentina.

#### PRUSSIA.

The Prussian Government has introduced a bill in the diet forbidding foreigners from acquiring mineral properties and operating mines within Prussia without the special permission of the King or the authorities representing him.

#### NORWAY.

An electric furnace for the production of pig iron on a commercial scale has been installed at Ludvika, Norway. The installation will include two high pressure furnaces of 2,500 horsepower each, two steel furnaces, 600 horsepower, and all will be supplied with a two-phase current. Later on additional furnaces will be installed.

#### UNITED STATES.

The anthracite miners of Pennsylvania at the convention in Scranton, Pa., decided to remain at work after April 1st and to allow the union's district executive boards in the Pennsylvania hard coal fields to continue their efforts to seek an agreement with the operators.

The production of the Lake Superior iron mines during February amounted to approximately 18,100,000 pounds fine copper, indicating a rate of production nearly 7 per cent. greater than for the same period a year ago.

The most perfect method known of eliminating arsenic from smelter smoke is in use at the Washoe smelter at Anaconda, Mont., and that does not prevent the escape of some arsenic from the smelter stack. While the company saves about 2 tons of pure arsenic daily, there still escapes through the stack and into the atmosphere about 10 tons of arsenic trioxide every day. The method employed for eliminating the arsenic is by flues and furnaces.

Several of the largest foundrymen and iron manufacturers in Milwaukee have formed the American Oxhydric Company, and work has been started on a factory. This company has purchased all the patent rights to a German invention for cutting and handling iron and steel by a secret gas process which

eliminates all the powerful and expensive machinery now necessary for this work.

Statistics of the output of steel in the United States last year exhibit a remarkable shrinkage. The total production was 14,018,000 tons, as against 23,363,000 tons in 1907, a decline of 9,345,000 tons or 40 per cent. The greatest contraction was shown in Bessemer steel, which fell off by nearly 50 per cent., from 11,668,000 to 6,117,000 tons. Open Hearth dropped from 11,550,000 to 7,781,000 tons, or 32 per cent.

#### SOUTH AFRICA.

An expedition, under Prince Boris, is being organized to visit Portuguese East Africa to recruit native labour to work in the South African mines.

During the year 1908 there were 1,429 diamond diggers working on the Vaal River. The output averaged 54½ carats, or £181 per claim holder. In 1907 there were 1,133 diggers, whose average was 46½ carats.

A company has been formed in Berlin to take over and exploit the diamond mining rights in German Southwest Africa, held by the German Colonial Company. Diamonds have been found along the coast for seventy-five miles from the Orange River.

Asbestos deposits of the Chrysotile variety are being developed in the Carolina district of Eastern Transvaal, and the Victoria district, Rhodesia. The crude produced is of good quality and 60 per cent. of it shows fibres over 1 inch long.

Something like 800 new stamps, and the equivalent of 400 more, in the shape of tube mills, will be installed in Rand mines during the first three months of 1909.

#### AUSTRALASIA.

The Australian Government's Iron and Steel Bounties Bill provides for the payment of a bounty of 12s per ton on pig iron made from Australian ore and on puddled bar iron and steel made from Australian pig iron.

#### MEXICO.

Three furnaces are in blast at the Chihuahua smelter of the American Smelting and Refining Company. It is stated that the diversion of ore hitherto going to the El Paso plant makes necessary the early erection of two additional furnaces whereby the plant's capacity will be about 1,250 tons daily.

It is announced that the Greene Mining interests in the State of Chihuahua, known as the Greene Gold-Silver Company, are to pass into the hands of an English concern, headed by the Rothschilds, of London. They have had their engineers in the field for several weeks.

Owing to a leakage from the river into the Natividad Mine, in Teojomulco district, it was necessary to blast out the bed of the river and cover a portion of it with cement. The work has been completed and the river turned back into its course.

## COMPANY NOTES.

#### DOMINION COAL CO.'S ANNUAL REPORT.

The annual report of the Dominion Coal Company shows that the net profits for the year were \$2,686,202, against \$2,094,539 in 1907, and the balance after interest and dividends was \$1,600,162. The total surplus for the year is \$4,253,471, against \$2,828,308 last year.

The output for 1908 was 3,555,068 tons, as compared with 3,541,253 tons for 1907, an increase of 13,815 tons. The navigation conditions were generally favorable to the company's operations, except during September and October, when the

smoke from forest fires seriously affected shipping in the St. Lawrence.

During the year the company's property generally has been efficiently maintained and mine developments steadily carried on. With the exception of three fires in surface buildings, where the loss was fully insured, there have been no serious accidents or unusual occurrences.

In the Lingan Victoria district, where the two pits, Nos. 12 and 14, have been recently opened, the developments for making them productive mines are being steadily pushed, and though the

Output from these pits is not at present required, the work has been carried on so that they may be ready for future requirements. The question of how far this work will be prosecuted in the immediate future depends on industrial conditions. The branch railway (seven miles in length) connecting this district with the main line of the company, and necessary sidings, are now completed. In this district a large reservoir, containing 300,000 gallons, and a small one of 700,000 gallons, have been constructed, and underground pipe system for supply water and protection has been laid.

Most careful attention is being paid to the getting of large quantities of coal, and special machinery is being provided to minimize breakage in shipping and stocking. The demand for the coal is increasing on account of its high calorific value, continues to be maintained in spite of competition by American operators to capture a portion of the Canadian trade in order to offset a lessened demand caused by dull trade conditions in their own country.

#### NIPISSING DIVIDEND.

The directors of the Nipissing Mines Co. have declared the regular quarterly dividend of 3 per cent. and an extra of 2 per cent. This is the same amount as was paid three months ago. The financial statement presented showed cash, bullion, ore

en route to the smelters, and ore at the mines to the value of \$1,009,000. On December 20th last the surplus was \$972,643.

Besides paying the extra dividend of 2 per cent., amounting to \$120,000, the company has added to its surplus, and in addition has about \$700,000 more ore in sight at the present time than it had on January 20.

#### LA ROSE BONUS AND DIVIDEND.

The directors of the La Rose Mining Co. have declared the regular quarterly dividend of 3 per cent. and a bonus of 1 per cent., payable April 20th.

#### LA ROSE CONSOLIDATED MINES COMPANY.

Notice is hereby given that a dividend of 3 per cent. for the quarter ending 28th February, 1909, and a bonus of 1 per cent. has been declared upon the outstanding capital stock of the Company, and will be paid on the 20th day of April, 1909, to shareholders of record at the close of business on 1st April, 1909.

By order of the Directors, the transfer books will be closed from the close of business on 1st April, 1909, and remain closed until 10 a.m. on 27th April, 1909.

Dated the 22nd day of March, 1909.

LA ROSE CONSOLIDATED MINES COMPANY,  
Per D. A. Dunlop,  
Secretary-Treasurer.

## STATISTICS AND RETURNS.

The coal shipments of the Nova Scotia Steel and Coal Company for February and the two months are as follows:—

|                        |        |
|------------------------|--------|
| February, 1909 .....   | 20,928 |
| February, 1908 .....   | 41,230 |
| Decrease, 1909 .....   | 20,302 |
| Two months, 1909 ..... | 56,773 |
| Two months, 1908 ..... | 88,980 |
| Decrease, 1909 .....   | 29,207 |

#### DOMINION COAL OUTPUT.

The output of the Dominion Coal Company during March was 251,585 tons, compared with 346,529 tons in March of 1908. For the three months to date the output totals 661,417 tons, compared with 946,286 tons for the corresponding period of 1908.

#### CUMBERLAND COAL CO.

The shipments for the month of March from the Cumberland Collieries were 35,435 tons.

#### COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt camp, and those from Jan. 1st, 1909, to date:

|                        | Week ending<br>March 20. | Since<br>Jan. 1. |
|------------------------|--------------------------|------------------|
|                        | Ore in lbs.              | Ore in lbs.      |
| Buffalo .....          | 45,350                   | 223,570          |
| Crown Reserve .....    | 115,520                  | 1,183,440        |
| Chambers-Ferland ..... | 117,440                  | 309,440          |
| King Edward .....      | 44,130                   | 98,050           |
| La Rose .....          | 195,000                  | 2,865,140        |
| Nipissing .....        | 351,080                  | 2,774,329        |
| Nova Scotia .....      | 79,420                   | 480,810          |
| O'Brien .....          | 77,200                   | 269,180          |
| Temiskaming .....      | 40,000                   | 470,000          |
| Trethewey .....        | 56,620                   | 525,550          |
| T. & H. B. ....        | 60,000                   | 564,060          |

Ore shipments to March 20, 1909, are 12,141,353 pounds, or 6,070 tons.

The total shipments for week ending March 13 were 1,181,360 pounds, or 591 tons.

|                        | Week ending<br>March 27. | Since<br>Jan. 1. |
|------------------------|--------------------------|------------------|
|                        | Ore in lbs.              | Ore in lbs.      |
| Crown Reserve .....    | 114,540                  | 1,297,980        |
| Cobalt Central .....   | 40,000                   | 161,755          |
| Chambers-Ferland ..... | 60,000                   | 369,440          |
| City of Cobalt .....   | 53,592                   | 579,522          |
| Kerr Lake .....        | 62,000                   | 327,142          |
| La Rose .....          | 260,000                  | 3,125,140        |

| Trethewey .....    | 129,000 |
| T. H. & B. ....    | 610,600 |
| Muggley Cons. .... | 72,900  |

Ore shipments to April 3, 1909, are 14,369,689 pounds, or 7,184 tons.

Total shipments for week ending April 3 were 1,270,826 pounds, or 635 tons.

#### CROW'S NEST PASS OUTPUT.

The output of the Crow's Nest Pass Company's collieries for the week ending March 26th was 16,605 tons, a daily average of 2,767 tons.

The output for the week ending April 2nd was 10,961 tons, a daily average of 1,827 tons. All the collieries were idle on the 27th, and that at Coal Creek on the 29th, discussing the new agreement.

#### BRITISH COLUMBIA ORE SHIPMENTS.

The following are the ore shipments for the week ending March 20th and year to date:—

##### Boundary Shipments.

|                   |        |         |
|-------------------|--------|---------|
| Granby .....      | 18,976 | 210,238 |
| Mother Lode ..... | 8,610  | 88,480  |
| Snowshoe .....    | 2,419  | 22,921  |
| Sallie .....      | 20     | 61      |
| Other Mines ..... |        | 1,502   |
| Total .....       | 30,025 | 323,202 |

##### Rossland Shipments.

|                            |       |        |
|----------------------------|-------|--------|
| Centre Star .....          | 2,660 | 28,925 |
| Le Roi No. 2.....          | 541   | 6,665  |
| Le Roi .....               | 758   | 9,218  |
| Le Roi No. 2, milled ..... | 260   | 2,700  |
| Other Mines .....          |       | 92     |
| Total .....                | 4,219 | 47,600 |
| Total .....                | 3,854 | 37,530 |

##### Slocan-Kootenay Shipments.

|             |       |        |
|-------------|-------|--------|
| Total ..... | 3,854 | 37,530 |
|-------------|-------|--------|

The total shipments for the past week were 38,098 tons and for the year to date 408,332 tons.

##### Granby Smelter Receipts.

###### Grand Forks, B.C.

|              |        |         |
|--------------|--------|---------|
| Granby ..... | 18,976 | 210,238 |
|--------------|--------|---------|

##### B. C. Copper Co.'s Receipts.

###### Greenwood, B.C.

|                   |       |        |
|-------------------|-------|--------|
| Mother Lode ..... | 8,610 | 88,480 |
| Other Mines ..... |       | 1,483  |
| Total .....       | 8,610 | 89,963 |

##### Consolidated Co.'s Receipts.

###### Trail, B.C.

|             |       |        |
|-------------|-------|--------|
| Total ..... | 6,936 | 68,936 |
|-------------|-------|--------|

##### Le Roi Smelter Receipts.

###### Northport, Wash.

|                   |     |        |
|-------------------|-----|--------|
| Le Roi .....      | 758 | 9,218  |
| Other Mines ..... | 181 | 3,403  |
| Total .....       | 939 | 12,621 |

The total smelter receipts for the past week were 35,461 tons and for the past year to date 381,758 tons.

The following are the ore shipments for the week ending March 27th, and year to date:

##### Boundary Shipments.

|                       |        |         |
|-----------------------|--------|---------|
| Snowshoe . . . 2..... | 2,733  | 25,655  |
| Mother Lode .....     | 8,116  | 96,596  |
| Granby .....          | 20,382 | 230,620 |
| Other Mines .....     |        | 1,563   |
| Total .....           | 31,231 | 354,433 |

##### Rossland Shipments.

|                            |       |        |
|----------------------------|-------|--------|
| Le Roi No. 2 .....         | 710   | 7,375  |
| Centre Star .....          | 3,928 | 32,853 |
| Le Roi No. 2, milled ..... | 260   | 7,960  |
| Other Mines .....          |       | 9,310  |
| Total .....                | 4,898 | 57,498 |

##### Slocan-Kootenay Shipments.

|             |       |        |
|-------------|-------|--------|
| Total ..... | 4,016 | 41,546 |

# Amatite B ROOFING

## Five Roofings Tested

GENTLEMEN: OAKFORD, PA, February 15, 1908.  
The Amatite Roofing you advised me to try has proved to be the best roofing I have on any of my chicken houses, having tested it for two years with four other roofings. Consequently, when I was compelled to buy a new roof on my wagon house, used Amatite.

If you see fit to use this letter as a testimonial, you will be doing the chicken fanciers a great benefit.

If any one wishes to see how the roofing lasts I will be pleased to have them visit my farm. Yours truly,

HILL CREST FARM, WILLIAM F. FOTTERALL.

This is the kind of letters which we get daily regarding Amatite.

Amatite has a surface of *real mineral matter*, which needs no painting. It will not rub off or wear off, as the coal tar pitch which holds it in place is a powerful adhesive.

The price of Amatite is very low. The smooth surface roofings sold at the price of Amatite are usually a one-ply or half-ply grade which is very flimsy and light in weight, and do not compare with Amatite, which is *five-ply*. Amatite has a double layer of Coal Tar Pitch, a double layer of wood felt, and a *real mineral surface*.

### Free Sample and Booklet

Send for a sample of Amatite and see what the mineral no paint surface looks like. You'll then understand why it is so much better than "painted roofing."

## Dominion Coal Company

Any person interested in the industrial life of Cape Breton or Canada, should have in his possession a copy of an illustrated volume entitled "Dominion Coal Co." by F. W. Gray. It contains 128 pages, giving a general description of mining and transportation.

The following are the subjects treated. General description of the Sydney coal fields: The mines of the Glace Bay Basin. The Phalen Seam. The Harbour Seam, The Emery Seam and lower seams of the Glace Bay Basin, The Lingan-Victoria areas, The fire-fighting organization and equipment, General and transportation. Every branch of work is illustrated and makes a splendid souvenir and and historical volume. MacLeod's Bookstores at Sydney and Glace Bay are the local selling agents, price \$1.00. The edition is limited all plates being destroyed.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

## FOR SALE

A partially developed Iron Pyrites Property, showing a large body of high grade ore, assaying from 40 to 52 per cent. The property is within a mile of Railway Station and a spur can be put in to mine side at a very small cost. Water power in the neighborhood can be easily utilized if desired. Shipments of ore have already been made from the property.

Further particulars may be obtained by applying to Box K. Canadian Mining Journal, Toronto.

## THE ROAD TO GOWGANDA

BY THE  
CANADIAN NORTHERN ONTARIO ROUTE

is thirty miles shorter than any other. Beginning February 2nd. through sleepers leave Toronto, 5 p.m. arriving Sellwood (Moose Mountain Iron Mines) next morning. (Breakfast served on train.) From Sellwood to Gowganda is one day's sleigh ride over the company's own road; comfortable road houses are stationed at easy distances and a fast freight and passenger service has been inaugurated with all points in Canada. # The Mining Manual 1909

By WALTER R. SKINNER

The Standard Reference  
Work on Mines

**Price 21/- Post Free**

1,600 pages. In Demy 8vo.  
Handsomely bound in RED Cloth

A record of information concerning

**MINING COMPANIES (Gold, Diamond, Silver, Copper, Tin, Iron and other Mines, Collieries, Land and Exploration Concerns, &c.),**

Arranged in three sections—**AUSTRALASIAN, AFRICAN, MISCELLANEOUS,**

Preceded by **TABLES OF CRUSHINGS**, and followed by lists of

**DIRECTORS, SECRETARIES, MINING and CONSULTING ENGINEERS, and MINE MANAGERS,**

Their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected, and a

**DICTIONARY OF MINING AND OTHER TERMS.**

The **Mining Manual** for 1909 contains particulars of over 3,500 Companies arranged in three sections, 450 Companies being AUSTRALASIAN (including Western Australia, Queensland, Broken Hill, Deep Leads, New Zealand, and Tasmania); 1,000 AFRICAN (including Transvaal, Cape Colony, Natal, Rhodesia, West Africa, Egypt); and 2,050 MISCELLANEOUS (including Siberia, Mexico, India, British Columbia, America, &c., and the Coal, Iron, and other mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts. Highest and lowest prices of the shares for the last four years, also latest price. The three sections extend over 1,100 pages.

Crushing tables and Gold Outputs from the principal mines are given at the commencement of the volume, showing tons treated monthly, results obtained and yield per ton; also annual yields.

The Lists of Directors (7,000), Secretaries (1,750), Mining and Consulting Engineers and Mine Managers (1,300), include their addresses and descriptions and names of the Companies with which they are connected.

A complete Alphabetical Index containing the names of 5,320 Companies, including many useful items of reference, occupies 43 pages.

# Geological Survey

## **PUBLICATIONS**

The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects.

### MARITIME PROVINCES

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

### QUEBEC

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Maps and reports dealing with portions of the province north of the St. Lawrence are also available.

### ONTARIO

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

### THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

### BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

### YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

### THE NORTH-WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of reports and maps are sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to *THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.*

### THE FOLLOWING REPORTS AND MAPS HAVE BEEN ISSUED DURING THE PAST YEAR

- |                                                                                                                                                                        |                                                                                                                                                                 |

# Ontario's Mining Lands

---

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,  
**Toronto, Canada.**

# PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

## Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement.

The price of prospecting licenses is \$5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only \$2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, \$10.00 per acre, and on lands situate less than 20 miles from such a railway, \$20.00 per acre.

Superficial products and building materials are sold \$2 and \$4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed

lands; work must be bona fide begun within two years and \$500.00 spent on each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of \$10.00 and a rent of \$1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts.

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with Mr. MILTON HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

**The Hon. Minister of Colonization, Mines and Fisheries**  
Parliament Buildings, Quebec.

# A Handy Reference List

We urge you to examine the books listed below with great care. Some are brand new—all are standard. We can supply any technical book in print

## Copper

### Principles of Copper Smelting

BY EDWARD D. PETERS,  
*Professor of Metallurgy, Harvard University.*  
612 pages, 6x9; cloth. \$5.00 (21s.) postpaid.

### Modern Copper Smelting

BY EDWARD D. PETERS.  
640 pages, 6x9; cloth, \$5.00 (21s.) postpaid.

### Copper Mines of the World

BY WALTER HARVEY WEED.  
376 pages, 6x9; cloth, \$4.00 (17s.) postpaid.

### Notes on Lead and Copper Smelting and Copper Converting

BY HIRAM W. HIXON.  
128 pages, 6x9. \$3.00 (12 6) postpaid.

### Pyrite Smelting

BY T. A. RICKARD,  
*Formerly Editor of THE ENGINEERING AND MINING JOURNAL.*  
210 pages, 6x9. \$2.00 (8 6) postpaid.

### Matte Smelting

BY HERBERT LANG.  
98 pages, 6x9. \$2.00 (8 6) postpaid.

## Lead and Zinc

### The Metallurgy of Lead

BY H. O. HOFMAN  
*Professor of Metallurgy, Massachusetts Institute of Technology.*  
600 pages, 6x9. \$6.00 (26s.) postpaid.

BOOKS BY WALTER RENTON INGALLS,  
*Editor of THE ENGINEERING AND MINING JOURNAL.*

### Lead and Zinc in the United States

6x9; cloth. \$4.00 (17s.) postpaid.  
(Price subject to change)

### The Metallurgy of Zinc and Cadmium

701 pages, 6x9; cloth. \$6.00 (25s.) postpaid.

### Lead Smelting and Refining

336 pages, 6x9; cloth. \$3.00 (12 6) postpaid.

### Production and Properties of Zinc

328 pages, 6x9; cloth. \$3.00 (12 6) postpaid.

## Gold and Silver

### The Chemistry of Cyanide Solutions

Resulting From the Treatment of Ores.

BY J. C. CLENELL  
164 pages, 6x9 cloth, illustrated, \$2.50 (10 6) postpaid.

### Practical Notes on the Cyanide Process

BY FRANCIS L. BOSQUI, PH. B.  
*Superintendent of the Standard Consolidated Mining Company's Cyanide Works, Bodie, Cal.*  
201 pages, 5½x9, illustrated, \$2.50 (10 6) postpaid.

### Stamp Milling of Gold Ores

BY T. A. RICKARD.  
6x9; illustrated. \$2.50 (10 6) postpaid.

### Hydrometallurgy of Silver

BY OTTOKAR HOFMANN.  
336 pages, 6x9; cloth \$4.00 (17s.) postpaid.

## Iron and Steel

### The Manufacture and Properties of Iron and Steel

BY HARRY HUSE CAMPBELL,  
*Metallurgical Engineer for the Pennsylvania Steel Company, etc.*  
Entirely revised in 1907. 641 pages; 6x9; illustrated.  
\$5.00 (21s.) postpaid.

### The Metallurgy of Iron and Steel

BY BRADLEY STOUGHTON,  
*Adjunct Professor of Metallurgy, School of Mines, Columbia University.*  
Fully illustrated; 6x9. \$3.00 (12 6) postpaid.

### The Metallurgy of Steel

BY HENRY M. HOWE, A.M., S.B., L.L.D.  
9x12; fully illustrated. \$10 (42s.) postpaid.

## The Manual of Fire Assaying.

BY CHAS. H. FULTON  
176 pages, 6x9, illustrated. \$2.00 (8 6) postpaid.

Immediately upon its publication the leading assayers, metallurgists and professors of the country hailed this as the best work yet issued on the subject. It substitutes exact knowledge for the rule-of-thumb.

## Ore Dressing

BY ROBERT H. RICHARDS,  
*Professor of Mining, Massachusetts Institute of Technology.*  
Two volumes. 6x9; cloth, 1250 pages. Profusely illustrated. Per set, \$10.00 (42s.) postpaid.

The standard authority on all classes of ore dressing by one of the leading mining authorities of the world.

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver; \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Minerals; or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579,039 the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
 Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 100,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

**Our Analyses Speak for Themselves.**

HAS. SIMISTER,  
General Superintendent.

J. D. HURD,  
General Manager.

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

W. W. CORY, Deputy of the Minister of the Interior

Sullivan "D-21" Hammer Drill in operation

## Sullivan Hammer Drills

are the most economical hammer drills to buy because they excel in **speed** and in **durability**.

The cost of power, labor and repairs per foot drilled with Sullivan machines is lower than that secured with other types.

All features of design, and all processes of manufacture, have been adopted only after thorough demonstration that each is **the** one which will contribute most to the speed of the drill or to its power of resisting wear and tear.

"D-21" air feed drills for stoping and raising.

"D-15" and "D-19" hand feed drills for block holing and trimming.

# The Mining Manual 1909

By **WALTER R. SKINNER**

**The Standard Reference Work on Mines**

**Price 21/- Post Free**

1,600 pages In Demy 8vo.,  
Handsomely bound in RED Cloth

A record of information concerning

**MINING COMPANIES (Gold, Diamond, Silver, Copper, Tin, Iron and other Mines, Collieries, Land and Exploration Concerns, &c.),**

Arranged in three sections—**AUSTRALASIAN, AFRICAN, MISCELLANEOUS,**

Preceded by **TABLES OF CRUSHINGS**, and followed by lists of

**DIRECTORS, SECRETARIES, MINING and CONSULTING ENGINEERS, and MINE MANAGERS,**

Their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected, and a

**DICTIONARY OF MINING AND OTHER TERMS.**

The Mining Manual for 1909 contains particulars of over 3,500 Companies arranged in three sections, 450 Companies being AUSTRALASIAN (including Western Australia, Queensland, Broken Hill, Deep Leads, New Zealand, and Tasmania); 1,000 AFRICAN (including Transvaal, Cape Colony, Natal, Rhodesia, West Africa, Egypt); and 2,050 MISCELLANEOUS (including Siberia, Mexico, India, British Columbia, America, &c., and the Coal, Iron, and other mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; calls dividends paid; and the financial position as disclosed by the accounts. Highest and lowest prices of the shares for the last four years, also latest price. The three sections extend over 1,100 pages.

Crushing tables and Gold Outputs from the principal mines are given at the commencement of the volume, showing tons treated monthly, results obtained and yield per ton; also annual yields.

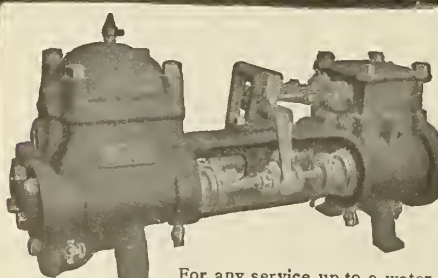

The List of Directors (7,000), Secretaries (1,750), Mining and Consulting Engineers and Mine Managers (1,300), include their addresses and descriptions and names of the Companies with which they are connected.

A complete Alphabetical Index containing the names of 5,320 Companies, including many useful items of reference, occupies 43 pages.

### AN ENGLISH ENGINEER'S ADVICE.

Under date of January 11th, 1909, Mr. William Frecheville, whose name is familiar to all Canadian mining men, wrote a letter of thanks to the Secretary of the Canadian Mining Institute. Summing up the impressions that he received during last summer's excursion, Mr. Frecheville emphasizes his opinion that large expansion is in store for the Canadian mining industry, both in established enterprises and in new fields.

To account for the small participation of English capital in Canadian mining, Mr. Frecheville cites the following reasons:—"Firstly, the results obtained by enterprises launched in England to work mines in Canada have not, as a rule, been encouraging. Secondly, the distance from the Canadian and American centres of capital to the Canadian mines is so much less than the distance from England, that the enterprising and alert Canadian or American gets there before the man from over the water has even a look in."

It would have brought out the truth more fully had Mr. Frecheville added that "the enterprising and alert Canadian or American" is not to be blamed for the undoubted lack of success on the part of English investors. English investments have been unsuccessful mainly because they have been blunderingly conducted. Instance after instance has occurred where capitalists from the Motherland have proved easy victims for promoters discredited in Canada. Time and again good British guineas have been squandered by a wasteful and incompetent management. Neither Canada nor Canadians can be blamed for this. The English investor needs, above all else, experienced and responsible mining engineers to guide him; men, indeed, of Mr. Frecheville's class.

"As matters now stand," concludes Mr. Frecheville, "the best procedure for English capitalists who contemplate interesting themselves in mines in Canada, would seem to be to have a resident agent there, who would keep them in touch with what is going on, . . . otherwise I am afraid that history will repeat itself, and what is brought over to London will by no means be 'the pick of the basket.'" Continuing, he recommends that only prospects that are at least promisingly developed, or mines already proved payable, be brought to the attention of London capitalists.

The general tone of Mr. Frecheville's letter is distinctly appreciative of Canadian mining. His good opinion counts for not a little, and his advice, simply and directly expressed, is worth more than pages of superlatives.

### GRAPHITE CONCENTRATION.

Mr. H. P. H. Brumell has for years constituted himself the champion of Canadian graphite. A long and discouraging fight was necessary before the Canadian product was granted a place on the world's markets. Also the problems that surrounded the separation of this mineral from its gangue were peculiarly difficult. To removing both the commercial and the technical obstacles Mr. Brumell has given his undivided attention. His paper, appearing on other pages of this issue, gives the reader a brief view of the history of the graphite industry in Quebec and Ontario, with especial reference to ore treatment.

The disseminated graphite ores of Labelle County, Quebec, and of Renfrew and Lanark, Ontario, are essentially graphite schists, in which quartz and feldspar predominate largely over other minerals. The small difference that exists between the specific gravities of these two minerals and that of graphite gives but little leeway for mechanical separation. Wet concentration formerly obtained altogether. The old stationary buddles, following wet stamping, gave a concentrate assaying 60 per cent., from a 10 per cent. ore. Among other devices, the Brumell separator replaced the buddles. Next the concentrates from the Brumell separator were dried and treated on Hooper tables. Now, at the mill of the Buckingham Graphite Company, the whole system is one of dry concentration.

Mr. Brumell characterizes this mill as being, to the best of his belief, the only one producing graphite commercially from disseminated ore. He further states that in such a plant ore carrying about 12 per cent. of graphite is concentrated up to from 75 to 86 per cent., and the concentrates finished to stocks assaying from 70 per cent. to 96.5 per cent.

The paper, "Graphite Concentration," is a worthy contribution to the literature published by the Canadian Mining Institute.

### THE COAL AND IRON-ORE SUPPLIES OF THE UNITED STATES.

Utilizing all available statistics and data, competent specialists have calculated that all the easily accessible coal known to exist in the United States will be exhausted by the middle of next century. The supply of high-grade iron ores now available will diminish to the vanishing point before 1950.

These statements, if even approximately correct, carry a tremendous lesson. Canada's iron ore resources are hardly touched. Her coal supplies, especially in the West, are sufficient for many decades. Yet neither commodity exists in exhaustless quantity. Canada will probably reach the highest development when our neighbour's annual outputs shall have begun to decrease. It is inevitable that we shall be called upon to supply both iron ore and coal for the greater part of

the continent. We shall be a richer and a greater people if, instead of crude iron ore, we sell iron and steel. To this end we must, to some extent at least provide for retaining control of our fuel resources.

The thought that Canada, through her mineral industries, must ultimately dominate the continent savours of arrogance—so not seldom does destiny.

### AN INVALUABLE INDEX.

The public has long been indebted to the American Institute of Mining Engineers for enriching the literature of mining with large numbers of monographs, essays, scientific discussions and descriptive papers of all kinds. These assume permanent form in the shape of large and costly annual volumes. Not many persons are lucky enough to possess, or to be able to purchase a complete set of these volumes. They are accessible however, in numerous public and reference libraries.

Scattered throughout these volumes are numberless special papers, allusions to processes, and all manner of material that is occasionally of vital interest to individuals.

Lately the Institute has published a General Alphabetical and Analytical Index, covering all the Transactions from Volume I. (1871) to Volume XXXV. (1904). The labour and expense entailed in compiling this 700 page index must have been enormous. The end justifies the time and expenditure lavished upon it.

To those who own sets of the Transactions, the Index opens up every page, and saves an infinity of time. For those who do not possess the annual volumes, the Index is the only possible substitute.

### IMPERIAL FEDERATION.

Seeking the co-operation of sister societies in Australia, Canada, and South Africa, the Institution of Mining and Metallurgy resolved to invite the President of these respective bodies to accept, ex officio, election as Honorary Members and Corresponding Members of Council of the Institution. The invitation was extended to the Australasian Institute of Mining Engineers, the Canadian Mining Institute, and the Chemical, Metallurgical and Mining Society of South Africa. It was readily accepted.

It may be noted that Corresponding Members of Council have the privilege of attending and voting at Council meetings.

This federation, loose though it may be, is certain to produce beneficent results. Membership in the Institution of Mining and Metallurgy gives definitive and honourable standing. Closer connection between the mining societies of the four principal sections of the British Empire will brighten and benefit each and all.

To us this seems to be the healthiest combination of Imperial sentiment and Imperial brains.

### THE LIFE OF A MINE.

There are several vital questions touched upon in a paper that appears in this issue, "The Valuation of Mining Areas on the Rand." The writer characterizes the practice of working rich reefs and poor reefs together on average grade as being financially unsound. To get the highest value out of a mine, it is necessary, in his opinion, that the grade in the early part of the mine's life should be higher than in the later years. This should be done, theoretically at least, in such a manner as to reserve the lower grade ore for future operations. In many mines such a course is impossible, but the principle has much to commend it. Mr. Wilkinson's paper should be read carefully.

It is unfair to isolate paragraphs from their context. Therefore we shall not quote farther. But we wish to direct particular attention to Mr. Wilkinson's remarks on the most profitable life of a mine.

### SAMPLES—NOT SPECIMENS.

A departure has been made in arranging the mineral exhibits at the Alaska-Yukon-Pacific Exposition which is shortly to open at Seattle. Heretofore it has been the custom to exhibit the finest picked specimens; a misleading and unconsciously dishonest proceeding. At the Seattle Exposition samples of from one hundred to four hundred pounds of ore will be displayed. Only legitimate mining concerns will be asked or permitted to exhibit. Along with each parcel of ore will be seen samples from the vein walls.

We hope that this will ring the knell of the spectacularly fine ore exhibit that represents, not the average ore of any mine, but the carefully hand picked specimen. Specimens are interesting enough mineralogically; but commercially they are mischievous.

### NOVA SCOTIA'S GOLD MINES.

In our last issue we published without comment a communication from Mr. T. A. Rickard, editor of Mining and Scientific Press. Mr. Rickard has taken exception to the attitude of the Government of Nova Scotia in regard to a special report written by him in 1905. Although written at the request of the Government,

this report has never been made public. In Mr. Rickard's opinion, this has done him an injustice.

More light is thrown on the subject in this number of the Canadian Mining Journal. We hope that our readers will follow the discussion closely. There are usually two sides to every question. Our own opinions will not be expressed until the matter is more fully threshed out.

### EDITORIAL NOTES.

An especially complete and excellent map of Rossland has just been issued by the Geological Survey of Canada. Director R. W. Brock is responsible for the economic geology, Dr. G. A. Young for the areal geology, and Mr. W. H. Boyd for the topography. The geological and cultural legends are particularly perfect.

The Geological Survey of Canada has also issued a geological map of Gowganda Mining District, the work of Mr. W. H. Collins. The diabase, conglomerate, granite, and Keewatin areas are approximately delimited. The geology, and there necessarily is but a scanty amount, has been worked out by Mr. Collins and Dr. W. G. Miller.

The mines of the Slocan district, British Columbia, have in the past made total dividend payments amounting to over four and one-quarter million dollars. The old Payne holds the local record—\$1,420,000. Next comes the Slocan Star, with \$575,000 to its credit. Six other mines have distributed total dividends ranging from \$400,000 to \$125,000. The district is attracting renewed attention this spring.

The Hon. Robert Drummond, in a speech before the Legislature of Nova Scotia, advocated the appointment of a Provincial Geologist. We heartily endorse this suggestion. Until such an official is appointed, Nova Scotia's mining administration will continue to be incomplete. The further recommendation, that the Government erect public stamp mills for the benefit of small operators, is sanctioned by usage in Australia and otherwheres.

## MINING AROUND KASLO, BRITISH COLUMBIA.

By E. Jacobs, Victoria, B.C.

Kaslo is the most important town in Ainsworth mining division, in which are situated a number of productive mines. It is on the west side Kootenay Lake, where Kaslo River enters the lake, and is the shipping terminus of the Kaslo-Slocan Railway.

Ainsworth was the pioneer mining district of West Kootenay, for, in 1889, the late Dr. George M. Dawson found mining being actively carried on at Ainsworth or "Hot Springs," as it was also called in earlier

years), which is situated a few miles lower down the lake than Kaslo.

Early accounts state that about 1890 hardy prospectors pushed their way up Kaslo River as far as Bear and Fish Lakes, on the summit of the divide, and searched for minerals on the adjacent mountain sides. In that year mineral claims were located by John (Lardo) McDonald and John Allen, who were hunting and trapping on what was known as Blue Ridge Creek,

ten miles west of Kaslo, but little was known of the value of these claims until after they had been visited in August, 1891, by Andrew Jardine, who returned to Ainsworth with samples of ore which assayed up to 171 oz. per ton in silver. Following this many prospectors examined the hills of the Kaslo slope, and passed thence over the divide to the Slocan slope where, on September 2nd, the Payne was located by John L. Seaton and Eli Carpenter. The finding of high grade silver ore here resulted in a genuine, old-fashioned mining stampede.

In his "West Kootenay Reminiscences," Mr. G. O. Buchanan, now and for years a resident at Kaslo, mentioned the plotting of Kaslo townsite in 1891, the forcing in to the heart of Slocan of wagon roads from Kaslo and Nakusp "by monumental energy;" the taking out to Tacoma of 10 tons of ore from the Dardenelles mine by Mr. E. E. Coy, who "brought back \$5,000 in gold coin;" the finding of "a big boulder containing 100 tons of galena," and the building, in 1895, of the Kaslo and Slocan Railway, this "giving an easy outlet to Kootenay Lake."

Coming down to the present, the following summary, while necessarily omitting records of much ma-

of California (father of the present owner of the Hearst newspapers) erected a small open-hearth furnace on the property and reduced some of the ore to bullion, but the low grade of the product and the difficulties of marketing it led him to abandon his enterprise. As the years passed it had other owners, including the Ainsworths, of Portland, Oregon. In the nineties it passed into the possession of Dr. W. Hendryx and his associates—Minnesota and Connecticut capitalists—who developed the mine and erected smelting works at Pilot Bay, eight miles lower down the lake. Failure followed, and for years the mine and smelter were held by the Bank of Montreal, until, in 1895, they were purchased by the Canadian Metal Company. Since then development, on a fairly large scale has been carried out, and ore, estimated at 300,000 tons, has been made available for stoping. Last year the erection and equipment of 200-ton concentrating mill was completed. During the latter half of the year approximately 18,000 tons of ore were milled and the product, some 2,200 tons of lead concentrate, was shipped to the smelter at Trail. The mill, which was designed by Mr. S. S. Fowler, general manager of the Canadian Metal Company, continues to do effective and economical

Bird's-eye View of Kaslo, B.C.—Distributing Centre of the Slocan.

terial progress and considerable productiveness during the years that have intervened since shipment of silver and lead ores in large quantity was commenced, will give some information of the progress made to date and present conditions.

The larger mines of Ainsworth mining division now producing ore are the Blue Bell, Cork, Whitewater and Deep, Lucky Jim, and Rambler-Cariboo. The mines of Ainsworth camp proper will not be included in this summary.

#### The Blue Bell.

While not on the Kaslo slope of the Slocan, the Blue Bell is in Ainsworth division, across the lake from and a few miles south of Kaslo.

This mine possesses historic interest in British Columbia. The big mineral outcrop was discovered in 1825 by David Douglas, a Scottish botanist, who, in that year, was engaged in making an examination of the flora and fauna in the vicinity of Kootenay Lake. Hudson's Bay Company men afterwards obtained lead here for bullets for their rifles. In 1864 George Hearst,

work, and the production of zinc, as well as lead, concentrate has been provided for. It is stated that notwithstanding the small silver content of the ore and the low price of lead, the mine and mill are being operated at a satisfactory profit.

#### South Fork of Kaslo Creek.

This part of the Kaslo district is reached by the Kaslo and Slocan Railway and thence by a good wagon road.

Among the mines on this creek, which have for years been ore shippers, and on which much development work has been done, are the Cork, Province, Montezuma, and Bismark. Other properties are the Revenue, Flint, Index, Black Fox, Bell group, Gibson, Silver Bell, Nome, Sturgis group, Pbs, St. Francis and Vera.

The Province and Montezuma were operated together by Kaslo men for a while, until last year, when a fire destroyed the Montezuma concentrator and lower terminal of its aerial tramway. Afterwards Nelson

men, well known in the Slocan as experienced mine operators, leased the Province mine, and further developed it by extending the tunnel from the adjoining Cork mine and raising 125 ft. in ore. The ore taken out was put through the Cork concentrator. Work was suspended for the winter, but this season 20 to 25 men will be employed in mine and mill. More de-

velopment work will also be done on the Cork property, which is owned by a French company.

These mines, the largest in Whitewater camp, are being worked under lease by J. L. Retallack, S. S. Fowler, and W. E. Koch, all well-known men who have been operating in Slocan district for years. White-

water camp is connected with Kaslo by railway, and last year the combined output of the Whitewater and Deep mines was about 2,300 tons of lead-silver concentrate and 8,000 tons zinc. Of the latter some 3,000 tons was made in 1907 and stored awaiting a suitable market. After a very successful year in 1908, the lessees arranged for work on a more extended scale in

development work will also be done on the Cork property, which is owned by a French company.

#### Whitewater and Whitewater Deep.

These mines, the largest in Whitewater camp, are being worked under lease by J. L. Retallack, S. S. Fowler, and W. E. Koch, all well-known men who have been operating in Slocan district for years. White-

water camp is connected with Kaslo by railway, and last year the combined output of the Whitewater and Deep mines was about 2,300 tons of lead-silver concentrate and 8,000 tons zinc. Of the latter some 3,000 tons was made in 1907 and stored awaiting a suitable market. After a very successful year in 1908, the lessees arranged for work on a more extended scale in

The Gold Commissioner for the Ainsworth and Slocan districts has his office at Kaslo. His jurisdiction extends north for some distance beyond Kootenay Lake, including the country known as the Duncan slope, in which direction important mining developments are expected to take place ere long, particularly on the Wagner group (recently bonded to Spokane, Washington, capitalists), and other promising properties in its vicinity on which ore bodes have also been discovered.

column headed "Amount," and the folio on which the personal account appears in the Ledger in the folio column of the amount of the invoice is entered in the debit column showing the proper heading, which must

the same as the Ledger Account chargeable with that particular expenditure. At the end of each month, the debit columns are all totalled, the total of each column being posted to the debit of the proper Purchase Account or Expense Account in the Ledger. The sum of all the debits, obtained by cross addition of the totals posted, must equal the total of the amount column. The invoices entered should be numbered consecutively and filed in the same order, and not as is very commonly done, filed under the companies'

names. The number of debit columns may be very large, some Purchase Journals having a separate debit column for every working account in the Ledger.

The Sales Journal, unlike the Purchase Journal, has the debit columns on the left hand side, and the credit column on the right hand side.

The following is a simple form of a Sales Journal for a Cobalt silver mine. For use at other mines, the headings of the Credit column will have to be changed to suit the character of the product :

## Sales Journal

[illegible]

The name of the purchaser and the amount are entered in their proper columns and each item is posted to the debit of the personal account in the Ledger. The corresponding amount is placed in one of the credit columns and at the end of the month the totals of the credit columns are posted to the credit of the different Sales Accounts, Silver Sales, Cobalt Sales, etc. The total of the credit postings must equal the total of the debit columns each month.

The General Journal is for all items that do not find their way into any of the other books. All cash transactions are taken care of in the Cash Book, all bills in the Bill Book, all incoming invoices in the Purchase Journal, and all outgoing invoices in the Sales Journal. Adjustments between accounts, opening and closing entries, sales of plant and stores, are all recorded in the General Journal.

At the end of the year inventories of stores, stationery, charges paid in advance, accrued charges, ore on hand, etc., are taken under careful supervision, all money values being at cost price. The accounts charged during the year with the purchases of any class of goods, is credited at the end of the year with the inventory of those goods on hand. The ore on hand is credited to the Sales Account. A new account is opened called "Inventory Account" to receive the debit for the total stock on hand. These entries are, of course, made through the General Journal.

After all adjustments have been made for the inventories the nominal accounts are all closed for the year into the "Profit and Loss Account." The form or making up this account differs with nearly every company. I would suggest a form as below; but it is almost impossible to make a hard and fast rule to follow in the formation of this account. However, I think some effort should be made to draw up a standard form showing the main features common to all. Blank spaces could be left to contain any additional items which the company insisted on showing in the Profit

and Loss Account. The same may be said of "Balance Sheets."

PROFIT AND LOSS ACCOUNT FOR YEAR  
ENDED.....

## CHARGES.

#### SUB-MARINE COAL MINING IN NOVA SCOTIA.

The question of sub-marine coal mining was legislated upon about thirty-two years ago by the Nova Scotian Government. Mr. H. S. Poole, then Chief Inspector of Mines for the Province, formulated the regulations which now are comprised under Section 54 of the Coal Mines Regulation Act. Mr. Foster, an English coal specialist, reported recently upon this section of the Act. He pointed out that the lapse of time has provided much additional experience and has brought about some changes of views. Hence, in some respects, the present regulations might be improved.

For instance, Sub-section (1) a, provides that no undersea workings shall be carried on with a less depth than 180 feet of solid cover. The lessee may, however, drive passage-ways for the purpose of mining the deposit only, under a cover of not less than 100 feet. Commenting upon this, Mr. Foster remarks that, having regard to the general nature of the beds overlying the seams in the districts adjoining the seaboard in Nova Scotia, it would not be advisable to alter this regulation. The exact thickness of the solid measures cannot be ascertained accurately in any case. Hence a considerable margin of safety should be provided.

Sub-section (1) b, provides that “a barrier of not less than 50 yards, 25 yards on both sides of the boundary lines of every lease, shall be left unwrought be-

tween the workings of each submarine seam.” The same regulation, more clearly expressed, appears Section 208, of “The Mines Act,” 1892. A clause the latter provides that a barrier of 25 yards is to left “within and along each of the boundary lines” any sub-marine lease. Mr. Foster recommends that this phrasing be substituted for the former. He marks that with deeper mining, wider barriers may be required, and that possibly power should be granted the Commissioner to require such extensions when considered necessary.

Clauses (c), (d), (e), and (f) are next discussed. (c) Provides that, where there is less than 500 ft. solid cover over the seam worked, the workings shall be laid out in districts of an area not greater than half a square mile, each district being enclosed by a barrier not less than 30 yards in thickness, which shall not be pierced by more than four passage-ways of a section area not greater than 4 feet wide by 6 feet high. The inspector may, if he thinks it necessary, permit the cross-section of the passage-ways to be increased to 6 square feet. (d) Restricts to one mile the length of any district when parallel to the general trend of the shore line. (e) Requires the approval of the inspector for any proposed system of working, also his sanction to any change in the approved system. (f) Provides that the opening of a new lift or level in a mine already working shall be deemed the commencement of new winning within the meaning of the section.

The first two regulations provide for the application, between the lines of 180 and 500 feet of cover, of a system known as the “panel system,” under which the area to be worked is divided into districts or “panels” surrounded by barriers through which as few holdings are made as may be considered absolutely necessary. The restricted dimensions of individual workings are designed as a safeguard against general flooding. Mr. Foster disapproves of the above restrictions. They cause great inconvenience in haulage and ventilation. He states that it is better to rely upon well proportioned pillars and careful regulation of the width of the working places and disposition of the same.

In general it is recommended that provisions (c), (d), (e), and (f) be eliminated, and that the conduct of undersea workings be regulated, not by hard and fast rules, but by a careful consideration of each set of circumstances.

Incidentally, Mr. Foster mentions the necessity of making surveys and levellings every three months. Soundings should also be taken at reasonable distances

## THE VALUATION OF MINING AREAS ON THE RAND

By W. Fischer Wilkinson, Member.

Paper read before the Institution of Mining and Metallurgy, London.

During recent years it has become the practice on the Rand, when forming new mining companies, to include a much larger area of ground than was the custom formerly, while several mines already formed into companies, have secured larger areas by amalgamation with neighbouring properties.

In laying out the first row of mines below the outcrop mines the area selected used to be about 200

claims (294 acres) for each mine with a milling plant of 200 stamps, the depth of the workings being from 1,000 to 3,000 ft. The standard adopted was a stamp a claim, the stamp being equivalent to an output of five tons per day. This area is now considered too small and companies with 1,000 claims and upwards have been formed.

These changes in the areas selected make it of in-

terest to consider the factors that decide the size of a mine and the principles upon which valuations should be founded.

As regards the question of size, it may be stated generally that the larger the area the less will be the capital expenditure on equipment and the less the working costs per ton. It is obvious that a large area lends itself to more economical development than a small one. Administration and general expenses, being spread over a larger tonnage, are proportionately reduced, while a great saving in capital expenditure is obtained by concentrating the reduction and power plant instead of having a number of small units.

The statistics of the Rand mining companies illustrate very forcibly the advantages of large units. The writer has compiled from the August, 1908, sheet of the Transvaal Chamber of Mines the following table, which shows the effect of large outputs as compared with small. The figures relate to 53 out of 63 mines in the Witwatersrand district. The 10 mines omitted are either small producers or mines which do not report working costs.

**Results of 53 Milling Companies on the Rand,  
August, 1908.**

| 20,000 to 30,000....      | 13              | 28.8                        | 17.0                        | 11.8                         |
| 30,000 to 40,000....      | 10              | 31.0                        | 17.0                        | 14.0                         |
| 40,000 and upwards        | 7*              | 32.6                        | 14.8                        | 17.8                         |

With regard to this table, it is advisable to mention, in order to prevent any misunderstanding, that the costs and profits shown are what are known as costs and profits on working account. Profit tax, depreciation and sundry expenditure, are not included. There is generally a difference of about 30 per cent. between the working profits shown and the profits distributed as dividends, that is, the dividends are 70 per cent. of the working profits.

The effect, therefore, of working on a large scale is to reduce working costs, and it is clearly an advantage to have a large area and to make the output as large as possible, paying due regard to capital expenditure and life.

In calculating the most suitable rate of working for any given area it is necessary, in the first place, to make an estimate of the probable tonnage and of the value of the ore. The Rand ore deposits are of such a character that fairly reliable estimates can be made, the reliability depending on the situation, size, amount of development, and records of neighbouring mines. Granting that calculations of this sort have been made, and that definite figures have been arrived at as to the amount of gold that the mine contains, the problem that then needs solution is the rate at which it may be most profitably extracted. The elements of the calculation are:—

1. Capital expenditure required for a given production.
2. The available tonnage and its value.
3. The cost of working.
4. The rate of interest required.

\*Included in this class is the East Rand Proprietary Company, which is rather a group of mines than one unit. If the figures of this Company are omitted the averages for mines milling over 40,000 tons per month would be six companies, yield 33.4s., costs 13.8s., profit 19.6s.

In mine valuations of this class it is time that is the important factor. As long as the gold is left in the ground, there is a loss of interest going on and, after a certain period, this loss of interest will exceed the cost of new shafts and equipment. An example will make this point clear. Suppose a property contains 1,000 claims and a tonnage of 20,000,000 tons estimated to give a net profit of 10s. per ton, and suppose the equipment is equivalent to an output of 400,000 tons per annum; the life would be 50 years and the annual income £200,000.

The present value of an income or annuity of £200,000 for 50 years, assuming that 6 per cent. interest is demanded and that a sinking fund to redeem capital was invested at 3 per cent., would be worth 14.5<sup>1</sup> years' purchase, or £2,900,000. If, however, the ground had been divided into two mines, or if the output had been doubled by increasing the reduction plant, the annual profits would have been £400,000 for 25 years.

The present value of this income is worth 11.5 years' purchase, or £4,600,000. There is therefore an increased value by doubling the rate of production of £1,700,000, which would far exceed the capital expenditure necessary to secure this increased rate.

This example indicates that in order to obtain the greatest value from any mining area containing definite values, as on the Rand, it is possible to calculate with some precision the most profitable rate of working.

The formulae necessary for calculating the most profitable life from a theoretical point of view have been given by Mr. Hellman,<sup>2</sup> Mr. Ross Browne,<sup>3</sup> Mr. R. N. Kotze,<sup>4</sup> and others.

According to Mr. Kotze, the most suitable life for a mine giving a 20s. profit per ton is about 11 years, and that for a mine with ore yielding a profit of 10s. a ton, 16 years. The definition that he gives of the most profitable life is that at which the ratio of increase of present value of profits to increase of working capital becomes unity. This would be the most profitable life theoretically. In practice, however, the life should be extended somewhat, and the ratio taken higher than unity. Mr. Kotze also comes to the conclusion that the larger the profit per ton the shorter would be the more profitable life if other conditions remained the same.

No doubt the calculations given in his paper would have to be modified to suit present conditions, the capital expenditure required for a given production being now less than at the time the paper was written. But as the effect of a decrease in the capital expenditure for a given output would be to decrease the, theoretically, most profitable life, the ideal life, on a 10s. per ton profit basis, may be taken to be under 16 years.

Mr. Ross E. Browne, who has also made calculations as to what is the most profitable life, arrives at the conclusion that 10 years is the ideal life.<sup>5</sup>

These calculations go to show that the life must be kept within bounds to obtain the greatest value out of a given area. The author wishes to emphasize this point because in recent amalgamations a long length of life has been put forward as a favourable feature.

It is no doubt a good thing for a mine to be worked on a large scale, but it does not follow that its life should extend beyond certain limits, which, as shown above, can be calculated.

<sup>1</sup>Inwood's Tables, p. 121a, 28th edit.

<sup>2</sup>Trans. Inst. of Min. and Met., vol. vi.

<sup>3</sup>Proc. S.A. Assoc. Eng., 1907.

<sup>4</sup>Trans. S.A. Assoc. Eng., vol. x., 1904-5.

<sup>5</sup>Trans. S.A. Assoc. of Eng., 1907.

The author does not wish it to be understood that he advocates the working of a mine strictly on the theoretical standard. In practice, it would, in his opinion, be unwise to go to the extreme limit. Even on the Rand there must be uncertainty as to the total tonnage by financial and labour considerations, factors which are variable and uncertain.

The safest course in practice would be to lay out the mine at the start for a production below the ideal production, but the aim should be to work ultimately to the scale of operations that calculations of total profits and total expenditure indicate as the most profitable.

In coming to the decision as to what is the best scale of operations, an important point to be considered is that of the most profitable grade to work to. The ore deposits of the Rand are such that the engineer can vary his grade within wide limits. He can increase his tonnage and lower his costs by including low-grade ore, that is, ore on which there is only a small margin of profit. Low costs and large tonnages do not, however, necessarily mean that the mine is being worked to the greatest profit.

To determine the most profitable grade it is necessary to calculate the present value of the total profits expected.

To illustrate this, the author will suppose that a mine has 1,000,000 tons which will give a profit of 20s. per ton, and that, by leaving some of the poorer ore in the mine, a production of 800,000 tons, giving a profit of 25s. per ton, can be obtained.

The question arises which is the more profitable grade to work, the high grade and the smaller tonnage, or the low grade and the larger tonnage. Assuming that the reduction plant will treat 200,000 tons per annum, the life will be either five years or four and the annual profits either £200,000 or £250,000. Calculating the present value of these profits on the annuity principle and assuming that 6 per cent. interest is required and that a sinking fund for the redemption of capital is invested at 3 per cent., the low-grade policy will show a present value of £806,000, and the high-grade £835,000. Consequently the high-grade is the more profitable grade to work to.

It will be observed that in all calculations as regards life or grade one of the most important factors is time; and it is this factor that carries great weight in valuations of deep level claims, which may be proposed for amalgamation with an adjoining property.

Some examples of the sort of valuation required may now be considered. Taking a simple case, that of the amalgamation of two undeveloped areas, each too small to be worked separately, but which together would give an area of suitable size for a mine, the valuation of the ground would depend on the Present Value of the profits to be derived on an assumed rate of working. It is usual to assume that the profit to be derived from the deepest ground would be less than that from the more shallow, partly on account of the profit being deferred and partly due to the assumption that working costs increase and consequently profits decrease with the depth of working. That is what is known on the Rand as the zone basis of valuation.

For convenience the ground is divided up into belts or zones parallel with the strike, and a value is calculated for each zone. The author believes in this system of valuation provided it is not carried to extremes. If carried too far, the value of the deeper claims is unduly

depreciated. The profits are discounted over too long a period, and a fairer way to value such claims would be to assume that they could be made productive earlier—which might be the case if a new shaft was put down—than if they had to wait for the exhaustion of all the ground above them. The relational value of claims has received considerable attention in South Africa, and those who wish to study this subject are recommended to read the paper by Mr. G. A. Denny, read before the S. A. Association of Engineers,<sup>1</sup> and the discussion that followed.

Another case that may be considered is that of the amalgamation of deep level claims with those of a producing and profit-earning mine. In this case the value of the deep claims to the producing mine will depend on the amount of tonnage still available in its own property—in other words on its life—unless the development of the deep ground can be taken in hand before the exhaustion of the upper ground.

The value of the deep level claims to the producing mine is the Present Value of the estimated profits at the time when the upper claims are exhausted. If the producing mine has still a long life before it, the value of the deep claims will be small, because the profits to be derived from the deep claims will be so long deferred.

It must also be borne in mind, when valuing claims, that there is a liability attached to them in the way of claim license, amounting to £3 per annum. The capitalized value of the claim licenses must be deducted from the capitalized value of the profits expected in the future. The factor time here again exercises an important influence, and if the realization of the profits is to be long postponed, the value of the claims will be small and may, in fact, be a minus quantity.

A third and somewhat more complicated case may now be considered.

As a rule, when an amalgamation of a producing mine with deep level claims is effected, an increase in production is arranged for, and the owners of the deep claims frequently contribute capital for this purpose. In making a valuation of the different interests in such a case, it would be necessary to calculate the Present Values of the estimated profits to be derived from different claims put in, and also to assess separately the value of the other assets, such as equipment, development and cash.

Both sides benefit by amalgamation owing to the speedier realization of the profits, and the case differs from that previously given in that the producing mine has here to consider the value of the extra profit that will accrue owing to the increased scale of operations which the capital of the deep block allows of, whereas, when no increase of production takes place, the producing mine has merely to decide whether the price put upon the present profits of the deep ground is sufficiently attractive.

There is one other point of great importance relating to mine valuation to which the author wishes to draw attention. It is well known that on the Rand there are rich reefs and poor reefs, as well as great variations in values in the reefs themselves. It is usual to work out the ore at an average grade, taking each reef out in its proper proportion. This system is financially sound.

Theoretically, to get the most value out of a mine, the grade in the early part of the mine's life should be higher than in the later years. In practice it is of

<sup>1</sup>Trans. S.A. Assoc. Eng., vol. 1, 1902-3.

course not possible to mine all the rich ore first and then return to the poor. Stopes or levels cannot be kept open indefinitely without great expense. At the same time the author thinks that some selection is possible, and that if the richest reefs and the richest sec-

tions of the poorer reefs were attacked first, a higher grade than the average could be obtained during the early years of the mine's life. A considerable appreciation in value would result from the adoption of this policy.

## GRAPHITE CONCENTRATION.

By H. P. H. Brumell, Buckingham, Que.

(Journal of the Canadian Mining Institute. Part of Vol. XII.)

Apparently simple, the solution of the problem of the concentration of the graphite contents of disseminated ore has proved extremely difficult, and it is only after many years of assiduous endeavour that we have arrived at the present modicum of success. As early as 1860 efforts were made to market Canadian graphite, and in 1867 the first mill for the dressing of the ore of Labelle County was begun in the Township of Buckingham. Since this initial effort, however, several mills have been erected, each, in succession, embodying some new feature and showing a gradual advancement from the early and crude method of buddling to a system of dry separation, now conceded to be the only logical method of treating so fugacious a mineral as graphite.

In the following brief resume of the work done in Canada, reference is made only to that ore so abundantly found in the County of Labelle, in the Province of Quebec, and sparingly in the counties of Renfrew and Markham, in Ontario. This ore is essentially a graphitic gneiss or gneiss carrying the graphite in more or less small lenticular particles and consists, in Labelle Co., of quartz, feldspar (usually orthoclase) and hornblende, with smaller quantities of pyroxene, sillimanite and graphite. The major portion of the gangue material is made up of quartz and feldspar, both having a specific gravity of about 2.5, while the gravity of Canadian crystalline graphite is 2.26, which leaves a very small margin on which to work. The remaining minerals are somewhat heavier, the specific gravity of hornblende being about 3, pyroxene 3.3 and sillimanite 3.2. Pyrite, with a gravity of about 5, is a negligible consideration, both on account of its greater weight and, the usually very small percentage in the ore.

The earlier attempts at concentration were all made with stationary buddles of a uniform type, the vat being about 16 feet in diameter, with a depth of 3 feet, the floor having a slope of 3 inches from the centre post to the edge. After being crushed in ordinary jaw crushers, the ore was stamped wet and fed to the buddles, with a considerable stream of water, entering them through short pipes from a revolving pan fixed to the lower end of the shaft, to which, also, was attached adjustable sweeps. These sweeps gave to the water and accompanying ore a gentle centrifugal motion, sufficient to carry away the lighter particles of graphite, which were deposited around the edge of the buddle, the heavier minerals being deposited near the centre, while the superfluous water escaped through a sluice gate at the side, control of which was effected by means of small swinging stops. When a buddle was filled it was allowed to drain and the material taken out by hand, the outer zone being of concentrates followed by a lining of seconds or middlings, the innermost portion consisting of tailings. These seconds were re-buddled a second and, sometimes, a third time. By the foregoing

method a very coarse separation was made, the concentrates rarely assaying 60 per cent., from a 10 per cent. ore. On drying, however, and passing the dried product over a series of screens, considerable quantities of the coarser sized flakes were obtained. Mills equipped in this way were erected and spasmodically operated at Oliver's Ferry in Ontario, and in Buckingham and Lochaber Townships in Quebec, but were unsuccessful; the non-success, as proved by later development, being entirely due to the system of disintegration and concentration. The ore, while soft and lubricous, is a peculiarly tough one and difficult to stamp, the stamps at times working the crushed wet ore into the shape of a cylinder with smooth polished sides, in which the stamp moved freely and ineffectively. As to capacity the best result obtained was about one ton per day per stamp (850 lbs.) and, as the buddles were emptied by hand, no practical mechanical means having been found, the entire process was found to be slow and much too costly. At several of the early mills keeves were used with but slight success. Experiments carried on at the mill of the North American Graphite Company in 1899 resulted in the replacing of the buddles by the so-called Brumell separator which, although a vast improvement on the buddles, soon gave way to pneumatic separators, the type first used being the Hooper concentrator. After the installation, at this mill, of the latter a fairly economical system was adopted and the ore was rolled dry. After crushing, the ore was dried in a revolving fuel dryer after which it passed through two pair of rolls, the overs of a 20 cloth being returned, and the resultant material sized in revolving screens. The sized material was then treated on the Hooper tables, the concentrates going to the finishing plant, while the seconds went to the Brumell separators, the concentrates of which were then dried and sent with those from the Hoopers to be finished. The foregoing has been superseded at the mill of the Buckingham Graphite Company, by the adoption of a system of dry concentration throughout, involving the abolition of the Brumell concentrator. The ore, after crushing, drying and rolling is brought by an impact screen to a certain degree of fineness, after which it is sized in a dry ore sizer; certain sizes being treated on a new type of pneumatic concentrator, other sizes going to the Hooper tables, while the finer ones are treated on a barrel concentrator. This mill is believed to be the only one commercially producing graphite from disseminated ore. While concentration has been the chief difficulty, there is another important feature in the manufacture of graphite, viz.:—finishing and grading to suit the various trades using the mineral. In a graphite mill there are three distinct departments for crushing, concentrating and finishing. In the former every endeavor is made to bring the ore to a

size wherein the particle is "freed" from its matrix without reducing its size, as in the markets a large sized flake commands a much higher price than the smaller ones, flakes coarser than 70 mesh being most in demand. The desirable condition is brought about, in a marked degree, by the use of rolls set in sequence of increasing pressure and the material scalped off as it is rolled to the desired mesh. In practice it has been found that a series of rolls bringing the ore to a maximum mesh of 20 gave the best results when, with proper care and manipulation, 80 per cent. of the material would be of a size between 20 and 80 mesh, 10 per

Buckingham Graphite Company's Mill, Buckingham, Que.

cent. between 80 and 150, and 10 per cent. allowed to go to the waste dump as too fine for economical treatment. After concentration the treatment accorded the material is continued with millstones of various materials, and revolving flour mill screens. In this treatment, as in rolling, care is taken to reduce the size of particle as little as possible, the object being to grind and reduce to a powder the associated foreign, and mainly silicious, materials, separation from which is effected by a system of scalping and the milling and screening is carried on until the residual material is a fine ground graphite, suitable for stove polish, foundry facings and paint, assaying from 25 to 75 per cent. With the plant as installed at the Buckingham Graphite Company's mill, the ore, carrying about 12 per cent. of graphite, is concentrated up to from 75 per cent. to 86 per cent. according to size, and the concentrates, in turn, finished, the finished or marketable stocks assaying from 70 per cent. to 96.5 per cent.

The following brief descriptions of the various plants in Ontario and Quebec, other than that of the Buckingham Graphite Company already described, embody all that the various owners have allowed to be known and are, in consequence, not strictly accurate as to detail.

#### The Buckingham Company.

This mill, which must not be confounded with that of the Buckingham Graphite Company, is situated on lot 26, range VI, township of Buckingham. The ore after a preliminary drying, was crushed and rolled with one Dodge crusher and one set of Krom rolls, after which it passed to screens and buhrstones. The entire product of the rolls, without any attempt at classification or concentration, was then run through buhrstones, reducing much of the gangue to a proper degree of fineness, after which it was run over silk bolting cloths, the graphite particles, which escaped the grinding operations, tailing over. This process was found to be so wasteful of the graphite contents of the ore that the business was closed down and the mill has now been idle for about ten years.

#### Anglo-Canadian Graphite Syndicate, Limited.

The works of this late company, formerly the North American Graphite Company, are situated on lot range VI, township of Buckingham, about one mile to the north-west of the foregoing and were operated on part dry and part wet principle. The ore was crushed then dried in a revolving fuel dryer, passing thence two pair of rolls, the overs of a 20-screen being returned and re-rolled. From the rolls the crushed ore passed to a battery of revolving screens, making four sizes which were then treated on Hooper concentrators, middlings going to two Brumell separators, the concentrates from the latter dried in a revolving steam dryer. The concentrates from both these sources were then finished with buhrstones and reels clothed with silk bolting cloths. These works were closed down about five years ago and have remained idle since.

#### The Diamond Graphite Company.

This mill is located on lot 14, range X, township of Buckingham, and is, at the time of writing, in process of reconstruction. The system first adopted was similar to that at the Buckingham Company's plant, no attempt at concentration being made. The ore, after drying, was crushed and rolled, going thence to flouring rolls instead of buhrstones, after which a system of screens was supposed to complete the operation. This method was found to be very wasteful and the management decided to replace the flouring rolls with Krom pneumatic mills and the change is now being made. No attempt at finishing the concentrates beyond screening is, apparently, contemplated.

#### The Bell Mines.

This mill is situated on lot 2, range V, township of Buckingham, and is the only one in Canada employing

Part of Finishing Plant, Buckingham Graphite Company, Buckingham, Q.

a wet method throughout. The ore, after crushing, reduced, with a heavy stream of water, in a Williams disintegrator to about 10 mesh, after which it is classified with wet screens and treated in Kendall separators. As far as is known no further treatment is accorded concentrates.

The development of this mill, which is the new in the district, is being watched with interest on account of the methods employed. Some of the concentrates obtained during the trying out of the plant were particularly good.

### The Calumet Graphite Mining and Milling Company.

The works of this company are located on lot 16, range II, township of Grenville. In this mill no attempt, apparently, was made at concentration, though but little is known of the methods employed. It is understood that no shipments of finished stock were made, the total production consisting of a quantity of ground ore, not sufficiently pure for even the lower uses to which graphite is put. The finished material referred to was the product of a pebble mill, installed for the avowed purpose, according to the monograph on "Graphite," published by the Mines Branch of the Department of Mines, of "cleaning and polishing of the graphite flakes." This method of "cleaning and polishing" would appear to have cleaned and polished the graphite to a vanishing point, as the resultant material was a grey, lack-lustre powder consisting of ground limestone and associated minerals, and graphite, of no commercial value. This

that in Germany and Austria, where the concentration extent, nearly all the mills operate on wet principle and in the United States on a combination of both wet and dry.

In the following brief descriptions of the various concentrators and methods of graphite ore dressing in Canada it is not thought necessary to enter into details as to the various types of crushers and rolls. The latter may be of any good type but should not be differential, while for the preliminary rough crushing all types of crushers have been used, the best service, in jaw crushers, being obtained with those of the Dodge type. On account, however, of the slippery character of the ore, particularly if it have a high graphite content, it has been found that better results were obtained when a rotary crusher was used, of which there are several types all equally suited to the work.

DIAMOND GRAPHITE COMPANY'S MILL, BUCKINGHAM, QUE.

View from South-East.

It is not now in operation. Reference to the use of pebble mills will be made further on.

### Globe Refining Company.

This mill, located at Port Elmsley, Lanark county, Ontario, was operated spasmodically until 1905, since when it is believed to have been idle. The ore, after crushing, was dried on a stationary sloping floor dryer and after being rolled was classified with revolving screens, from whence it went for treatment on Krom jigs over which it was milled on millstones and their accompanying screens. In practice the Krom jigs were not found to be satisfactory and in consequence taken out and the finished product made by flouring rolls and reels, similarly to the process until lately prevailing at the Diamond Graphite Company's mill in Buckingham.

For the purpose of this paper it is not thought necessary to enter into descriptions of the various concentrating methods in vogue outside of Canada, except to say

The following, in brief, are the various concentrators which have been, or are being, used in Canada.

### Wet Separators.

Buddles.—Already described.

Keeves.—Tubs, usually, of three or four feet in depth, by three feet in diameter with removable sweeps attached, at right angles, to a vertical shaft in the centre. The ore, usually fines, was fed, with a sufficiency of water, until the tub was filled, a strong centrifugal motion being imparted by the sweeps. When the charge was completed the sweeps were elevated and while the contents were settling the tub was knocked on the outside, the slight jarring effect keeping the lighter graphite in suspension longer than the heavier gangue minerals. The operation lasted about three hours, when the water was drained off and the sediments removed by hand. In a three foot keeve there was usually a deposition of about fifteen inches, the graphite, in a fair state of con-

centration, being found uppermost. The operation was slow and, requiring hand labour, was expensive and was never adopted to any great extent.

**Brumell Separator.**—This is a method, rather than a machine, and relies upon the floatability of graphite, when dry, upon, rather than beneath, the surface of

over into a settling tank, hopped to the centre, where it is wetted, and drops through an opening into a spiral steel conveyer enclosed in a tube and inclined at an angle of  $45^\circ$  from whence it is fed automatically to a revolving steam dryer. The water passes under and over several stops and eventually escapes through a screen at the op

BRUMELL SEPARATOR.

water. The apparatus employed is a square wooden box, twenty feet in length by four feet wide and five feet deep, filled with water and with a surface current extending across its width, obtained by jets projected against the side at an upward angle of  $45^\circ$  and about nine inches below the surface. This box is hopped along the sides, the cants throwing the tailings into a worm conveyer which, in turn, conveys the refuse to an elevator with perforated bucket, the chain of which

posite side. This apparatus, while very economical as to power and capacity and entirely automatic, is, at best, only a rough concentrator rarely bringing a 10 per cent. ore up to 65 per cent., and in consequence is not now in use.

**Kendall Separator.**—This machine, patented in 1902, is the invention of Mr. C. Kendall and is now in use at the Bell mine in Buckingham township where it is being practically tested. In principle it relies on the affinity

DIAGRAM OF BUDDLE.

actuates the conveyer. The dried ore is fed to the surface near the side over the jets by means of a spiral steel conveyer enclosed in a tube with a longitudinal slot the entire length, and, passing over a glance board, is dropped about one half an inch in a thin curtain to the water. The graphite which remains floating is carried

of oil for graphite and consists of a vertical cylinder terminated at the base with an inverted cone. The ore is thoroughly mixed with a superabundance of water and before entering the separator is again mechanically mixed with a heavy gravity mineral oil. The whole, while in an agitated state, is fed down to near the base

f the machine by an inner tube which extends to a height of about ten feet above the cylinder. The graphite, with its adhering particles of oil, rises to the surface and flows in a thin film over the edge of the cylinder to a launder which carries the pulp off to a settling tank from which the oil is syphoned to be used again. At the bottom of the cone is a swinging gate valve, which allows the water and tails to escape and acts, at the same time, as a regulator to the thin film of oil and graphite flowing over the lip of the cylinder. In principle this method is undoubtedly good but time will tell as to its practicability. Great difficulty will, no doubt, be encountered in keeping a regular height on the continuous charge in the cylinder and the problem of entirely ridding the graphite of the oil will, probably, be difficult to solve.

#### Dry Separators.

**Labouglie Separator.**—In 1876 a patent was issued to Joseph Labouglie, of Buckingham, which covered the adaptation of an ordinary fanning mill. The dried ore was dropped before the blast of a fan, similar to a grain winnowing fan, and the lighter graphite was

their respective bins, the finer smaller particles from the uppermost and the heaviest from those near the bottom of the shaft. Needless to say this method was not a success.

**Krom Pneumatic Jig.**—This was probably the first pneumatic machine to be used in Canada and has been found, while good in principle, to be somewhat too delicate in operation for practical work. It consists of a chest containing a swinging door blower giving rapid pulsations of air which is carried to tubes of silk bolting cloth arranged close together to form a bed whereon the concentration is made and as the continuous charge of ore is carried forward in strata a knife edge adjustable tail board is supposed to skim off the graphite, allowing the tails to drop under or behind. There are many details as to arrangement of feed and delivery of heads and tails which need not be gone into here. With an uniform ore and an absolutely steady power the machine would, no doubt, be very satisfactory, but these are conditions difficult to obtain. The monograph on "Graphite," already referred to, thus naively refers to the machine: "The apparatus, when

GLOBE REFINING COMPANY'S MILL, PORT ELSLEY, ONT.

View from South-East.

supposed to be projected further than the heavier gangue minerals and receptacles were arranged at increasing distances for the collection of the various products. It is not necessary to say that the machine was never adopted and mention is only made here to illustrate the early date at which efforts were directed towards dry separation.

**Nappenburg Separator.**—This apparatus was installed at the mill later owned by the Buckingham company, but at the time of its installation was owned by Messrs. Pew and Weart. In principle it was similar to the separator just described but much more elaborate and consisted of a deep shaft or well about two feet by one foot with blasts arranged at various points directed horizontally from the wider side across to screens of various mesh. The dried ore was fed in a curtain from the top, dropping down in front of the blasts, which were supposed to project the lighter graphite across to and through the screens. These blasts were arranged in increasing strength from top to bottom and the various screens had sprouts which were supposed to, but unfortunately never did, convey the concentrates to

carefully watched, works satisfactorily, but it has no power of self regulation. This causes the machine, if fed more rapidly than normal, to contaminate the concentrates, the flakes with the tailings, and if fed less rapidly to lose concentrates in the tailings. And, further, if the feed be regular in quantity but the percentage of graphite variable, then the rise in percentage will enrich the tailings and the fall in percentage will contaminate the heads."

**Hooper Pneumatic Concentrator.**—This machine consists of a flat chest containing a diaphragm actuated by eccentrics on a driven shaft running horizontally beneath the chest, and this chest, in turn, is surmounted with a movable deck of a peculiar design, the two separate parts being connected with a hollow ball and socket joint. The eccentrics, which are adjustable, act upon the diaphragm causing pulsations of air to pass up through the ball and socket joint and through a second diaphragm immediately below the deck which consists of a cast iron grating covered with broadcloth. Over this grating is the concentrating top, consisting of a cast iron frame with parallel strips

of sheet brass extending diagonally from side to side, and these in turn are surmounted by another set of parallel strips diagonally in the other direction. The ball and socket joint permits of the top being set at any vertical or lateral inclination. The ore is fed to the upper end of the concentrating top and is aided in its travel to the lower end by the rapid pulsations of air which pass up through the broadcloth effecting at the same time a concentration according to gravity. The lower brass strips, or riffles, carry the heavier portions to the lower side of the deck while the upper brasses or channels carry the lighter or top stratum diagonally to the upper side. At the discharge end of the deck are finger pieces which guide the various products to their respective receptacles. These machines require very accurate sizing of material and when once set as to eccentric throw, speed and vertical and lateral inclination, require no further care beyond cleaning the broadcloth bed which should be done about every five hours.

**Barrel Concentrator.**—This machine has given excellent results as a rough concentrator and consists of a

either two, four or six and the object is, presumably, to crush to a dust the foreign material and to trust to luck that the particles of graphite slip through untouched. In practice it has been found that a very large proportion of the graphite was ground, as well as the gangue material, and that it was not possible to obtain a particularly high grade of graphite by this method.

**Pebble or Tube Mills.**—Probably the most erroneous idea prevalent among inexperienced graphite producers is that these mills can be used for the cleaning of graphite from the gangue and for the polishing of the graphite flakes. In the monograph on "Graphite," already referred to, appears the following very misleading statement: "This mill on account of its great efficiency and smooth action has found its way into graphite mills of recent date; it is used for polishing and grinding graphite flakes and can be so adjusted that the latter are freed from sand; it replaces effectually the old buhrstone mill, while other mills either crush, twist or cut the material."

No more misleading statement could possibly have

NORTH AMERICAN GRAPHITE COMPANY'S MILL, BUCKINGHAM, QUE.

View from West.

revolving cylinder set with a slight downward inclination and having straight narrow flanges extending throughout its length. The discharge end is open while the feed end fits, as snugly as possible, into a square stationary chest to the opposite side of which is connected the suction pipe of an ordinary exhaust fan. The ore is fed into the upper end of the cylinder and, by means of the flanges, is carried up and dropped across the exhaust draft in the cylinder, the inclination finally discharging the tails at the lower end. From the fan the concentrates are blown into a dust collector or bag house for further treatment. It is unnecessary to state that for this treatment it is essential that the ore be very carefully sized.

Someone has written somewhere that "separation without classification is damnation" and this certainly is the case where pneumatic concentrators of any type are used.

**Flour Mill Rolls.**—This treatment of graphite should not properly be classed as concentration as the operation consists merely in rolling with smooth rolls set with a slight differential. These rolls are in sets of

been made as these mills are used only for fine pulverization and are usually equipped with an exhaust, with dust collector, which draws off the material when ground to the required degree of fineness. In point of fact these mills have replaced all other fine grinders in the various larger works in the United States where it is required to "kill the flake," a not very simple matter, and certainly not a desideratum with producers of flake.

#### RESCUE APPARATUS IN AUSTRIAN MINES.

The Austrian Mining Board has recently issued an interesting regulation relative to the use of rescue apparatus in mines.

Some approved form of rescue apparatus shall be kept in working order, and in a readily accessible place, at all mines. In order to keep the valves and fittings from being attacked by rust, the oxygen bottles must be perfectly dry inside, and recharged with dry oxygen by a dry pump. In the most dangerous class of mines five sets of rescue apparatus must be kept when not

ore than 200 men are at work per shift, 10 sets for shifts of from 200 to 400 men, and 15 for shifts of over 400 men. Each apparatus must be capable of supplying oxygen for 1½ hours. In non-fiery mines the number of apparatus is fixed at five, irrespective of the number of men per shift, except that where there are below 200 an apparatus supplying oxygen to last one hour is permitted.

Where a number of dangerous mines, employing over 200 men per shift are situated close together, all the apparatus in excess of the five sets necessary to equip one corps of rescuers may be kept at a central station of easy access. Rescue stations must be furnished with a duplicate source of oxygen bottles and number of safety lamps of some permitted type; one lamp for testing the presence of fire damp is necessary when the other lamps are electric. A trained man must be placed in charge of the station and made responsible for the good order and maintenance of the equipment. The men trained for rescue parties must be medically examined, and each corps must use the apparatus at least every six months.—Eng. and Min. Journal.

### THE RECENT ASBESTOS MERGER.

The Amalgamated Asbestos Corporation, Ltd., has been granted a charter under the laws of the Dominion of Canada to acquire, control and operate various asbestos producing properties situated on the line of the Quebec Central Railway, in the Province of Quebec.

#### Capitalization.

The capitalization of the merger is \$25,000,000, made up as follows:—

|                                                                                                                                                                                                                                                                                                                                                             |              |

- The British-Canadian Asbestos Company.
- The Standard Asbestos Company.
- The Dominion Asbestos Company.
- The Union Asbestos Company.
- King Asbestos Mines.
- The Beaver Asbestos Company.

And the Bell Asbestos Mines by a contract for the entire production over and above the requirements of the Keasbey and Mattison Company, manufacturers of asbestos products, and the affiliated companies controlled by Dr. R. V. Mattison.

#### Board of Directors.

The following named gentlemen have consented to serve as directors; Henry M. Whitney, Boston, president, the British-Canadian Asbestos Company, Ltd.; Hon. Robert Mackay, Montreal, director Canadian Pacific Railway Co., Bank of Montreal, the Royal Trust Co., and Bell Telephone Co. of Canada; Howard Ellery Mitchell, Philadelphia, of Cramp, Mitchell & Shober, bankers; Richard V. Mattison, M.D., Ambler, Pa., president Bell Asbestos Mines, Keasbey & Mattison Co., Asbestos Shingle, Slate & Sheathing Co., Asbestos Manufacturing Co. of Lachine, Canada and the First National Bank of Ambler, Pa.; E. B. Greenshields, Montreal, director Bank of Montreal, Grand Trunk Pacific Railway Co., the Royal Trust Co., and the Standard Life Insurance Co.; president Greenshields, Ltd.; Harry A. Berwind, Philadelphia, Berwind-White Coal Mining Co.; Thomas McDougall, Quebec, director and chairman of the Board of Directors, Quebec Bank; director and vice-president, the Shawinigan Water & Power Co.; Theodore W. Cramp, Philadelphia, of Cramp, Mitchell & Shober, bankers; Hon. James M. Beck, New York, ex-Assistant United States Attorney-General; trustee Mutual Life Insurance Co. of New York; director National Copper Bank of New York; William McMaster, Montreal, vice-president and managing director Montreal Rolling Mills, director Montreal Telegraph Co. and the Dominion Iron & Steel Co.; R. H. Martin, New York, president Kings Asbestos Mines; Hugh A. Allan, Montreal, president Montreal Telegraph Co., director Allan Line Steamship Co., Ltd., Merchants' Bank of Canada, Grand Trunk Pacific Railway Co.; C. Hartman Kuhn, Philadelphia, director Girard Trust Co. and Insurance Co. of North America; H. H. Melville, Boston, vice-president Canadian Northern Quebec Railway Co., director Shawinigan Water & Power Co.

#### Production.

Asbestos mining is now the most important mineral industry in the Province of Quebec. The presence of asbestos in the Eastern Townships has been known since 1847, but it was not till 1877, thirty years later, that the deposits were worked. During the last thirty years the aggregate production has had a value of more than twenty million dollars, and at the present time the Province of Quebec produces between 85 and 90 per cent. of the world's supply.

The following returns indicate the growth of the industry. The production of low-grade material was greatly increased by the introduction of mechanical concentration in 1892-3-4:—

| Year.        | —Asbestos—  |              | —Asbestic—  |           |
|--------------|-------------|--------------|-------------|-----------|
|              | Short tons. | Value.       | Short tons. | Value.    |
| 1880.....    | 380         | \$24,700     | .....       | .....     |
| 1881.....    | 540         | 35,100       | .....       | .....     |
| 1882.....    | 810         | 52,650       | .....       | .....     |
| 1883.....    | 955         | 68,750       | .....       | .....     |
| 1884.....    | 1,141       | 75,097       | .....       | .....     |
| 1885.....    | 2,440       | 142,441      | .....       | .....     |

| 1896.....    | 10,892      | 423,066      | 1,358       | 6,790     |
| 1897.....    | 13,202      | 399,528      | 17,240      | 45,840    |
| 1898.....    | 16,124      | 475,131      | 7,661       | 16,066    |
| 1899.....    | 17,790      | 468,635      | 7,746       | 17,214    |
| 1900.....    | 31,621      | 729,886      | 7,520       | 18,545    |
| 1901.....    | 32,892      | 1,248,645    | 7,325       | 11,114    |
| 1902.....    | 30,219      | 1,126,688    | 10,197      | 21,631    |
| 1903.....    | 31,129      | 915,888      | 10,548      | 13,869    |
| 1904.....    | 35,611      | 1,213,502    | 12,854      | 12,850    |
| 1905.....    | 50,669      | 1,486,359    | 17,594      | 16,900    |
| 1906.....    | 60,761      | 2,036,428    | 21,424      | 23,715    |
| 1907.....    | 62,241      | 2,484,768    | 28,296      | 20,275    |
| 1908.....    | 65,156      | 2,551,596    | 25,239      | 25,829    |
| Totals ..... | 541,105     | \$20,823,382 | 175,002     | \$250,638 |

The prevailing prices of the product have been as follows:—

|           | Crude No. 1. | Crude No. 2. | No. 1 Fibre. | No. 2 Fibre. | No. 3 Fibre. |
|-----------|--------------|--------------|--------------|--------------|--------------|
| 1901..... | \$125.00     | \$80.00      | \$50.00      | \$30.00      | \$16.00      |
| 1902..... | 150.00       | 90.00        | 55.00        | 35.00        | 18.00        |
| 1903..... | 175.00       | 100.00       | 60.00        | 37.50        | 20.00        |
| 1904..... | 225.00       | 110.00       | 75.00        | 40.00        | 22.50        |
| 1905..... | 225.00       | 125.00       | 85.00        | 45.00        | 25.00        |
| 1906..... | 250.00       | 150.00       | 100.00       | 50.00        | 27.50        |
| 1907..... | 275.00       | 175.00       | 110.00       | 55.00        | 30.00        |
| 1908..... | 275.00       | 175.00       | 110.00       | 55.00        | 30.00        |

During the year 1908 the companies included in this consolidation supplied over 65 per cent. of the world's production and about 73 per cent. of the production of Canada.

The amalgamated properties are fully equipped with modern quarrying and milling plants of most substantial character. The mills, most of which are new, have a daily capacity of about 4,500 tons of mill rock. Over five miles of railway owned by the company and equipped with eight locomotives and 220 cars and other equipment, connect the quarries with each other and with the mills. A considerable portion of the towns of Thetford and Black Lake are built on land belonging to the company, and many of the dwellings used by employees are owned by the company.

According to Mr. Obalski, of the Quebec Department of Mines, of the total quantity of asbestos exported,

United States takes 78 per cent., Great Britain 13, and Germany 8.41.

The engineers who reported upon the properties and the proposed consolidation were Mr. E. C. Bacon, C.E., of New York, and Mr. Fritz Cirkel, M.E., of Montreal. Mr. Bacon built the first asbestos mill in 1891, on the old Glasgow-Montreal property at Black Lake. His forte is mechanical engineering. Mr. Cirkel has specialized in asbestos for years. He has written a valuable monograph on the subject, and is now about to bring out a second monograph. His work for the Federal Mines Branch has given him a national reputation.

## BOOK REVIEW.

**General Alphabetical and Analytical Index—Transactions of the American Institute of Mining Engineers. volumes I.-XXXV. (1871-1904), 700 pages. New York, N.Y. American Institute of Mining Engineers, 1907.**

This volume, an octavo of 700 pages, is now ready for delivery. By its aid, any subject treated or alluded to in the Transactions can be instantly tracked. The names of persons, mines, works, towns, etc., have been included; and abundant cross-references and classified sub-headings have been added to facilitate rapid consultation. Thus, the student remembering the name but not the locality, or the locality but not the name, or neither the name nor the precise locality of a gold mine, can find it under "Gold Mines," or under either of the other heads. For a more extended statement of the nature and use of this Index, which is intended specially for the benefit of those who do not possess complete sets of the Transactions, and who consult the Library by correspondence, see the Bi-Monthly Bulletin for September, 1907. The price of the Index bound in cloth is \$5, delivery charges prepaid. Half-morocco binding costs \$1 extra.

## EXCHANGES.

**The Iron and Coal Trades Review, April 16, 1909.—**

The Review, glancing over the world's iron ore trade, has this to say about Canadian enterprises in Brazil: "Brazil is still undeveloped, but when the time comes for more active exploitation of the fields it will be found that the best deposits have been picked up and are no longer available at tempting prices. It is fortunate, however, that the Brazil deposits have largely passed into Canadian or English hands." Reference might have been made by the Review to New Brunswick, Nova Scotia, Ontario, and British Columbia as future sources of iron ore supply.

**The Engineering and Mining Journal, April 24, 1909.**

—Referring editorially to the general subject of conservation of natural resources, our contemporary dwells upon the function of government officials in this direction. "The Government (United States) itself has an excellent opportunity to lead and show the way by reducing extravagances in its own affairs. Among minor matters it might cease undertaking to teach us how to gasify coal, operate gas engines, and burn coal under boilers without smoke, and otherwise, multiplying unnecessarily the standard, but long-existing, literature of engineering. The matter of economy in production may safely be left to the engineers of the

country. Government officials can no more show them how to improve their methods of mining and smelting, extracting coal, etc., than they can teach their grandmothers to suck eggs."

#### The South African Mining Journal, March 20, 1909.

—In this number is a report of the Stope Drill Elimination Trials. The surface elimination trials, the first competitive test to which all entries were subjected, lasted for four weeks. Drills were entered from nearly all the chief mining countries of the world. The object is to determine the best stoping drill for Rand conditions. In average inches drilled per minute, average cubic feet free air used per minute, and average cubic feet free air used per foot drilled, reciprocating machines won the highest place. But hammer-drills ran a close second, and displayed some advantages that may overbalance the slight disadvantage in efficiency.

Throughout the trials it was evident that a jet of water through hollow steel makes the best dust allayer. Only two machines drilled over  $2\frac{1}{2}$  inches per minute of total time.

**Mining and Scientific Press, April 17, 1909.**—Legislation limiting a day's labour to eight hours is making headway in the Western States. Our contemporary has something to say on the point that the movement is based, not upon the merits of a shorter day's labour, but upon false reasoning that attributes to mining and metallurgic work exceptional unhealthfulness. "Personally," says the Mining and Scientific Press, "we do not believe that the peril of silicosis in a gold mine is greater than the danger of infection by many diseases from the street dust we complacently tolerate in our cities; we would prefer the risk of the miner to that of the motorman or city teamster. . . . The real question is a shorter day's labour for the workingman, but it were wiser to fight it out fairly on its merits, or else to construct police regulations operating equitably on a basis not limited to single industries."

#### PERSONAL AND GENERAL.

Dr. A. E. Barlow, after giving evidence before the Mining Committee, spent a day in Toronto.

Mr. Joseph Houston, of the Right of Way mine, has been appointed consulting engineer for the Nipissing Mining Co.

Mr. Bruce R. Warden, engineer to the Nicola Valley Coal and Coke Company, has returned from a trip to England.

Mr. J. W. Bryant, one of the Tyee Copper Company's engineers, has returned to Victoria, B.C., from a trip to Mexico.

Mr. Selwyn G. Blaylock, superintendent of the St. Eugene mine, East Kootenay, B.C., is back from a trip to the Province of Quebec.

At Lake George, York County, New Brunswick, an antimony smelter has started operations. The Lake George ore is first subjected to concentration.

Mr. J. D. Hurd, of Fernie, B.C., general manager of the Crow's Nest Pass Coal Company, is on a business visit to Chicago, St. Paul and other places.

Mr. Frank A. Ross, manager for the Daly Reduction Co., Hedley, B.C., has returned to the property from New York City, where he was on company business.

Mr. Chas. Emmerson, manager of the mines of the West Canadian Collieries, Ltd., recently left Bellevue, Alberta, for a three months' trip to the Old Country.

Mr. H. E. West, who has spent the winter at Cobalt, is leaving for El Oro, Mexico, to rejoin the staff of R. M. Raymond, general manager of El Oro Company.

Mr. R. E. Harris, president of the Nova Scotia Steel and Coal Company, sailed for Europe in connection with the financial reorganization of the company.

Mr. J. M. Ruffner, manager of the North Columbia Gold Mining Company, of Cincinnati, Ohio, has gone north to operate the company's hydraulic gold mines in Atlin, B.C., for the ensuing season.

Mr. J. J. Harpell has returned to Toronto after an extended tour through Great Britain and Europe. Mr. Harpell's mission was to investigate the trans-Atlantic mineral markets, especially to discover the probable demand for the products of Canadian mines.

Mr. G. A. McCarthy resigned recently his position as chief engineer of the Temiskaming and Northern Ontario Railway to become superintendent of construction of a new power company, which will supply electric power to the Cobalt mines.

A committee representing the Canadian Mining Institute appeared before the Commons Committee on Mines and Minerals, April 21st. They suggested that the administration of all mineral lands be transferred from the Department of the Interior to the Department of Mines. Surface rights, they argued, should be separated from mining rights. The members of the committee were Dr. A. E. Barlow and Messrs. B. A. C. Craig, J. M. Clark, and J. B. Tyrrell.

The Mining Committee of the Federal House is composed of the following members:—Messrs. Blondin, Boyce, Burrell, Chisholm (Antigonish), Congdon, Conmee (Chairman), Devlin, Goodeve, Herron, Lanctat (Richelieu), Loggie, Lortie, Macdonald, McCarthy, McCoig, McIntyre (Strathcona), McMillan, Maddin, Prowse, Rhodes, Smith (Nanaimo), Smyth, Stratton, Templeton, and Turriff.

Travellers will find the new form of Travellers' Cheque now being sold by The Canadian Bank of Commerce a great convenience for obtaining money away from home or in foreign countries. They can be bought at any office of the Bank for sums of \$10, \$20, \$50, or \$100 as may suit the purchaser. Hotels and banks everywhere in the civilized world will cash them, and no dispute can arise as to identification or the amount of money which the traveller may expect to obtain for them. On the face is printed the sum in the principal European currencies which the holder is entitled to receive, and in Canada and the United States they pass everywhere at par.

At the regular April meeting of Council of the Canadian Mining Institute the following gentlemen were elected to membership:—Members—Barney, Wm. G., Latchford, Ont.; Bourne, F. J., Cobalt, Ont.; Glendinning, Geo., 142 Dowling Ave., Toronto, Ont.; Neelands, E. V., Hargrave Silver Mines, Ltd., Cobalt, Ont.; Vance, J. F. C. B., 411 Nelson St., Vancouver, B.C. Associates—Barthe, L. H., Cobalt, Ont.; Campbell Amos, Quebec, Ont.; Drury, Chas. LeB., 122 Wellington St. West, Ottawa, Ont.; Machin, H. A. C., Kenora, Ont.; Morrison, G. F., 401 Traders Bank Bldg., Toronto, Ont.; Pellatt, Sir Henry M., A.D.C., Toronto, Ont.; Perault, Ovila S., 900 St. Antoine St., Montreal, Que.

On Monday evening, April 19th, a small mining boom occurred in the neighbourhood of Elm Avenue, Rosedale, Toronto. A number of mining men had received a week's notification that certain conditions could have to be met before claims could be staked.

Twelve prospectors succeeded in staking and recording one claim each. The assessment work was varied. Much moisture was encountered on several of the claims. Only one valuable discovery was made, and that one disappeared before April 20th.

## CORRESPONDENCE.

To the Editor of the Canadian Mining Journal.

Dear Sir,—In your issue of March 15th I read with great interest your preliminary note on the electric melting experiments conducted by J. W. Evans, and am surprised to find—

“Mr. Evans built a 2,000 Kilowatt Alternating Current Generator and Exciter, the power supplied to run them being furnished by a 5 h.p. gasoline engine.”

Probably the reader's surprise was no greater than that of our friend, Mr. Evans, who has never, so far as we know, sought distinction in the field of electrical engineering and construction.

Mr. Evans' friends have all been looking forward to remarkable results from his researches, and had implicit confidence that he would add much to our knowledge of this work, but we were astonished to learn—as he must also have been—that during the past winter a 2,000 kilowatt, or approximately 2,700 horse power generator, had been constructed in his laboratory.

While this in itself would have been an engineering achievement of much note, it loses interest beside the fact that we see he has been able to transcend so far what we have heretofore considered natural laws that he has driven this huge machine with a 5 h.p. gasoline engine. Such results would be most gratifying if you have correctly reported the situation, and apparently the power field may be revolutionized at any time.

The Journal has always been the exponent of conservatism in figures, but this time it looks as if some one on the staff must have been listening to prospectors who have sold their claims for so many millions that figures lost all significance to a dazed mind.

Just what was the Journal trying to say that Mr. Evans did do. Yours truly,

H. R. KIRKPATRICK.

Toronto, April 16th, 1909.

### RECIPROCITY IN COAL.

To the Editor of the Canadian Mining Journal,  
Toronto, Canada.

Dear Sir,—On both sides of the line the question has been revived in an acute form, of interchange between the two neighboring countries of the most important article of commerce—coal. I expressed my views upon the subject in an address which I gave last year to the students of the Kingston Mining School. I said:

“On our continent the railroad has proved the greatest nation building instrument, provided there by a vigorous and honest human force to use it. This has been abundantly proven in the United States, and the history of the Canadian Pacific is a further confirmation of it. Without the railroad running from ocean to ocean, the Confederation would have been a hopeless failure, and the North-West would have been still a great buffalo range.

“When we look upon the railroad from a miner's point of view, it is one of the greatest forces for na-

tional unity that exists. Statistics express this. If you take the different classes of freight carried by the railroads of the United States you will find that while the volume of each differs slightly in different sections, the average is as follows:—

|                              |        |
|------------------------------|--------|
| Products of Agriculture..... | 8.56%  |
| Products of Animals .....    | 2.32%  |
| Products of Mines .....      | 53.09% |
| Products of Forests .....    | 11.34% |
| Manufactures. . . . .        | 14.81% |
| Merchandise. . . . .         | 4.06%  |
| Miscellaneous. . . . .       | 5.92%  |

“This means that the products of the mines are necessary to support the railroads, and that, on the other hand, the mines could not possibly exist without the aid of the railroads. They are, therefore, mutually dependent one on the other. But when we look into the movement of the principal article carried, namely, coal, of which there were mined in the United States last year 470 million tons, we recognize the political importance as much as the industrial importance of this branch of national industry. Before the war the country was divided into two bitterly hostile camps of protectionists and anti-protectionists. The South demanded free trade, in order to feed and clothe her slaves cheaply. New England, being then the only manufacturing section, as vehemently demanded high protection. At that time the West consisted of the states, now composing the easternmost section of the Middle West, devoted to farming alone. With the development of coal mining and the expansion of the railroad system, all this has changed. The South is manufacturing its own cotton, and turning cotton seed into oil and other by-products, as well as creating the second largest centre of the iron manufacture on the continent. And the West, with Chicago in the lead, is rapidly outstripping New England, and its manufacturing energy is almost exceeding its agricultural activity. New England is, in fact, making less progress than any other section of the country, and why? Because she has no coal. Transportation cost has been so reduced that she can supply herself from Pennsylvania—400 to 500 miles distant—with this indispensable commodity. But coal lies nearer to her hand than Pennsylvania, and this fact is influencing her political position towards this country, and creating in New England alone a strong reciprocity sentiment. When we look at home we find that two provinces—Ontario and Quebec—the most populous and the richest members of the Confederation, suffer from the same complaint—lack of fuel; and yet across the lake in Pennsylvania and Ohio there is such abundance of this very life blood of industry that in order to reach it 30,000,000 tons of iron ore are brought to their coal fields from mines to the west of distant Lake Superior. In fact, Ontario is nearer fuel than the seaboard of Pennsylvania itself; but is cut off from this indispensable agent to the full development of her industrial life by a political line

drawn through the centre of the St. Lawrence, and of Lakes Ontario and Erie. If more reasonable international trade policies were adopted, and the continent's resources as a whole were utilized by its people as a whole, certain industrial disabilities on both sides of the political line would immediately disappear. Nova Scotia would supply New England by cheap ocean navigation alone; and Pennsylvania and Ohio coal would be transported across the lakes to Ontario. Montana, Idaho and Dakota, especially Montana and Idaho, for their smelting operations, need coke, which the Crow's Nest coal fields of British Columbia can supply in full abundance; while the Pacific Coast States must draw their coke from coal fields 2,000 miles distant, either across the mountains, or by boat from Vancouver, unless they prefer to import it from New South Wales.

"It seems almost incredible that two industrious peoples should set at defiance the first laws of economic science, and allow sectional political interests and prejudices to stand in the way of what is so conspicuously to the interest of both."

The coal deposits of Cape Breton and Nova Scotia enjoy the unique advantage of being actually on the seashore, and, therefore, being able to use the ocean and the river as the great highway for the distribution of their products. The effect of the reciprocity treaty of 1854 showed what a beneficial influence the removal of trade restrictions in the United States had upon the coal mining industry of Nova Scotia by raising the output from an insignificant figure to 500,000 tons a year. The present output of 6,000,000 tons is small when compared with the geographical position which the maritime coal fields hold to the markets of the northern section of the Atlantic seaboard. Were trade restrictions removed, I have no doubt whatever that the output would increase by leaps and bounds—not in hundreds or thousands—but in millions of tons. It cannot be doubted but the beneficial effect upon every industry in Ontario of the free importation of Pennsylvania and Ohio coal would be incalculable. There may seem to be some good selfish reason why the coal miners of Pennsylvania and Ohio should object to the introduction of Nova Scotia coal to New England factories; but it is strange short-sightedness on the part of the coal miners of Nova Scotia to refuse to exchange the limited market which they have on the St. Lawrence for the unlimited market which the North Atlantic seaboard states would offer them.

Yours truly,

JAMES DOUGLAS.

99 John Street, New York, April 6, 1909.

### THE LUMBER SITUATION IN GOW GANDA.

To the Editor of the Canadian Mining Journal.

One of the most important requisites, in the development of a mining camp, is plenty of lumber. Now, Gow Ganda has been most abundantly provided, by nature, with the best of the forest trees, pine and spruce, yet man has decreed that, in regard to cheap lumber, it shall be no better off than an inaccessible desert region devoid of forest growth.

Gow Ganda is in an extensive timber reserve, called the Temagami Forest Reserve. In this area the white pine is reserved in perpetuity. The pulpwood, spruce, balsam and other timber belongs to J. R. Booth & Co., having been bought from the Ontario Government many years ago at a low price.

During January of this year, a man named Knowles took a complete saw-mill outfit into Gow Ganda and started cutting timber. This green, rough lumber found an immediate sale at \$45 to \$55 per thousand feet. A week or two after starting operations, orders came that all cutting of timber must stop, and building operations were at a standstill in Gow Ganda till about March 10th. Then the mill started up again, although the cutting of timber for cabins was prohibited. Now, however, \$60 to \$75 per thousand feet was charged for the different grades of lumber, and it developed that Knowles was not allowed to cut any spruce by the J. R. Booth Co., and was charged the exorbitant amount of \$18 per thousand board feet, on the stump, by the Government for the pine.

Now conditions and expenses of running a saw-mill at Charlton and Gow Ganda are practically identical, if anything conditions favor Gow Ganda, as even the slabs and sawdust find an immediate sale at good prices. Yet at Charlton the mill owners can cut and sell, presumably at a profit, lumber for \$17 per thousand. At Gow Ganda the same grade costs \$70. The cost of transportation between Charlton and Gow Ganda by sleigh is about \$50 per thousand feet.

One can hardly blame the Gow Ganda mill-owner for charging a good price for his lumber, but the action of the Government is inexcusable. Besides charging a reasonable stumpage fee, they should expropriate some of the holdings of the J. R. Booth Co., whose refusal to sell is hampering the development of the country. This may seem to be an unwarrantable interference with vested interests, yet under the circumstances it is justifiable. The only difficulty is that the Government has shown such an example of greed, in its dealings with Gow Ganda interests, that it would be hypocrisy on its part to dispossess private citizens for the same fault.

One can only regret the terrible forest fires which are inevitable in that district this summer. Prospectors should realize the wicked waste they are guilty of in setting fire to large areas of fine timber, under the fallacious idea that it helps prospecting. The fire rangers in the district will have more than their hands full coping with fires due to accident and carelessness, but when fires are deliberately set out their efforts will be useless, and instead of a forest reserve there will be a desolate brule.

JAMES D. CUMMING.

113 Bedford Road, Toronto.

### A REPLY TO MR. T. A. RICKARD.

To the Editor of the Canadian Mining Journal.

Sir,—I have read with great interest Mr. Rickard's letter, in your last issue, concerning his report on Gold Mining in Nova Scotia, which was made by him on behalf of the Nova Scotian Government.

I happen to have been a member of the committee of the Mining Society of Nova Scotia referred to by Mr. Rickard. I was unable to take any active part in selecting a mining engineer to make the investigation, having been absent from the Province, both when Mr. Rickard was selected, and during the period of his investigation. At a later time I had the privilege of reading Mr. Rickard's report. I am unable to speak as to the official attitude regarding this report, and as to views of other members of the committee, and, therefore, am only stating my own personal opinion.

I was very much surprised to see that Mr. Rickard had either misunderstood, or had gone beyond the scope of what I had supposed were the original bounds of his investigation, as first discussed. As I personally originated the movement for this investigation, I may be allowed to speak as to its purpose.

It was intended that the Nova Scotian goldfields should be looked over, all data bearing on supposed similarity to Bendigo gold occurrence noted, as also the dissimilarities, and suggestions and advice given as to future developments. This part of report was fully carried out. The points to which I personally take exception, and which, in my opinion, rendered it impossible to publish the report, at least in the form in which it was submitted by Mr. Rickard, were the almost personal criticism of individual resident man-

agers, and the opinion stated with regard to a gold mine that was in active operation. Mr. Rickard had a perfect right—as a private individual—to form his own judgment on any mining operation coming under his view, but placed, as he was, in a semi-public position, such an opinion could hardly fairly be published.

I think Mr. Rickard will agree that a government official (even a temporary official) is not expected to express opinions for publication as to methods, values, or in any way directly affecting the status of a mining company, particularly a going concern.

I have no doubt that other members more conversant with the whole matter will more ably state their side of this question.

Yours faithfully,

GEORGE H. GILLESPIE.

Madoc, Ont., April 22, 1909.

## INDUSTRIAL PAGE.

### THE BEHREND WET FLOTATION AND CONCENTRATING SYSTEM.

#### I.

In the concentration of ores by the ordinary wet methods, it is an accepted fact that the losses that take place with many ores are due mainly to the nature of the mineral constituents being flaky and scaly and characterized as sectile which float upon the surface of the water. This float, due to its scaly nature, does not become thoroughly wet and is, therefore, irrecoverably

After many years of careful experimentation, Mr. Samuel K. Behrend, the inventor of the Behrend Dry System of Concentration, has evolved and invented a most complete method for the economical treatment and handling of these ores.

In this method of treatment, which consists essentially of feeding dry crushed ore upon a current of water, floating away the fine rich mineral, recovering same by filtration or some similar method and reconcentrating the tailings on a shaking table or trough of special construction, the losses are reduced to a

Wet Flotation and Concentrating Table—Behrend System.

lost by being carried away in the drain. Among the ores that this is particularly true of are graphite, galena, stibnite, chalcopyrite, tetrahedrite, sylvanite, molybdenite, argentite, stephanite and native silver. In the concentration of these ores, losses vary from 35 per cent. to 65 per cent. of the original mineral constituent.

Many methods and devices have been proposed and tried in the endeavor to overcome and cut down these losses, but up to the present, all have been unsuccessful.

minimum; in most cases a recovery of over 90 per cent. being readily secured at extremely low cost of operating.

By referring to the sketch, it is seen that the ore is fed from the hopper H on the distributor D, which delivers a steady stream of ore upon the surface of the water introduced at W in the tank below and travels in the direction shown by the arrows. At the same time a downward current is induced by having the spigots S open to such an extent as to allow the tailings to be discharged, and permit a minimum of

water to be discharged at O into the settler or filter F. Owing to the nature of the material, the gangue, together with granulated mineral constituents sink, while the scaly, flaky mineral, is carried forward, meeting obstructions at a, b, c, d, which tear the surface and permits the water to act upon the floating mineral, cleansing the mineral from its impurities and delivering it in practically a pure state to the filter.

The tailings are discharged through the spigots at the bottom into a common launder L, which feeds into the head of the concentrating trough T.

This trough is made up of a series of small compartments, each of which is a concentrating table in itself, equipped with a riffled surface and a valve of special construction. Between each section is placed a ducker (d), which compels every particle of ore to become thoroughly wet. The trough is equipped with an adjustable eccentric E, which imparts to it a rapid reciprocating motion. Means are provided to increase or decrease the pitch of the trough at both ends. The rapid motion of the table stratifies the mineral and permits it to be discharged continuously from the valves  $v^1$ ,  $v^2$ ,  $v^3$ ,  $v^4$ ,  $v^5$ , while the tailings are carried along with the rush of water and discharged from the end of the trough, clean of mineral.

The riffles covering the floor of the trough, are placed on canvas with 1" centres, running from a feather edge at their upper portion to  $\frac{1}{2}$ " high placed across the trough and just in front of the ducker. This permits of a bedding of mineral to be carried at all times, the valves being set so as to permit the discharge of clean mineral only.

As can be readily seen, any mineral escaping the first compartment, is caught in the second; that which escapes the second is caught in the third, and so on down. When the material reaches the discharge end, it must be absolutely clean and free from values.

The first two, three or four compartments will produce shipping concentrates, while the remainder will form a middlings product, to be returned to the head of the table to be reconcentrated.

It is evident that a machine of such simple construction requiring so little power to operate, and having so great a capacity, can be readily adapted to the concentration of mill tailings, it being merely necessary—in most cases—to attach the trough to the tailings launder. A recovery of a large portion of the present losses may be confidentially expected.

**Allis-Chalmers Company.**—This company's Bulletin No. 1433 describes the Allis-Chalmers Prospecting Mill, for free gold ores. The mill consists of a three-stamp battery complete with all framework and equipped with power. It constitutes a light, compact, easily transportable plant. The stamps weigh 250-lb. each. The mill is arranged to be operated in one battery by belt from stamp countershaft. The equipment includes:—

- 1 high mortar, weight 1,000 lb., arranged for copper amalgamation plates in front and back, screen frame seat planed and foundation holes drilled to templet.
- 1 wood screen frame fitted to mortar.
- 2 wrought iron keys.
- 1 steel screen—3 steel shoes—3 steel dies—3 cast-iron heads—3 stems of mild steel—3 tappets—3 double seams—1 heavy-hammered iron cam shaft—2 wrought iron collars—2 heavy corner cam shaft boxes—1 cam shaft pulley—1 jack shaft—2 jack shaft boxes—3 iron sockets—3 finger pieces—1 set of wood guides, and complete frame shafting, water pipes, copper plates, etc.

The power usually furnished consists of 1 three-horse-power combined vertical engine and boiler.

We are pleased to note that one of our advertisers, Messrs. Belliss & Morcon, of Birmingham, England, has just obtained a contract for what we understand is the largest single ventilating fan set in Great Britain. The combination consists of a Belliss triple expansion engine of 1000 B.H.P., running at about 200 r.p.m., and coupled direct to one of Messrs. Davidson & Co.'s sirocco fans of 154-inch diameter. This plant will be installed at the Cambrian Collieries' Mines in South Wales; the engine being similar to two 750-K.W. electric sets put in some months ago in the same collieries for general power and electric work."

Messrs. Laurie & Lamb, Montreal, Canadian agents for Messrs. Belliss & Morcon, Birmingham, England, have recently received an order from the Toronto University for a Belliss Engine for use in the Hydraulic Laboratory of the University. This engine will operate a couple of centrifugal pumps by belt.

## SPECIAL CORRESPONDENCE

### NOVA SCOTIA.

**Glance Bay, April 19.**—The Opening of the 1909 Season.—The Department of Marine at the end of the second week in April reports the Gulf as practically clear of ice, and it looks as if navigation would open quite early. Sydney harbor has been clear of ice for some time past, and a number of the season's charter vessels are arriving in port. The Dominion Coal Company will probably send the first steamer to Montreal about the 20th of April. The prospects are for an average season, and it is not probable that the St. Lawrence shipments from any of the Nova Scotian collieries will exceed those of previous years. The aggregate output of the Nova Scotian coal companies will in all probability be slightly below those of 1908.

The output of the Dominion Coal Company to the end of March amounted to 663,454 tons, which compares with 946,286

tons during the first quarter of 1908, being a decrease of 282,000 tons.

The slackness in trade was alone responsible for the decreased production, and all the other coal companies have been affected in like manner. The thing that has most materially affected the coal sales for this season has been the general feeling of uncertainty as to the actions of the United Mine Workers of America. This uncertainty, coupled with the persistent competition which has been waged against Nova Scotian coals in the Upper Provinces by United States coal operators, has rendered it more difficult for the sales agents of the Nova Scotian coal companies to negotiate their contracts than was ever the case before.

In the present very depressed state of the bituminous coal trade in the United States many of the operators have been

willing, and even glad, to send coal into Canada at a price which has netted them a loss, in order that their mines should not stand idle. Coal sales have been made at prices which net the operators under 90 cents at the pit mouth. It is hardly to be expected that the leaders of the United Mine Workers of America in Pennsylvania will raise any very strenuous objections to an agitation in Cape Breton which enables the Pennsylvania sales agent to push his sales, and provides that energetic gentleman with so useful an argument at the season when contracts are usually renewed. In fact, the disturbance of confidence which has resulted from the agitation raised in Cape Breton by the paid delegates of the United Mine Workers of America has so admirably suited the purposes of the United States coal sales agent in Canada as to bear a distinct resemblance which exists between the effect and the cause. The leaders of the U. M. W. A. are men of sufficient foresight to anticipate the possibility of strained relations between their as yet unrecognized union and the anthracite operators. It is hardly necessary to point out the advantage which would accrue to the U. M. W. A. in the event of a strike in the anthracite country if they were able to put an embargo on Nova Scotian coal shipments to the disaffected region, for in such a case it cannot be doubted that the leaders of the U. M. W. A. would consider that "it would conserve the best interests of the U. M. W. A." to call out the miners in Nova Scotia.

As previously remarked, the reflex of this unfortunate agitation, even if nothing more serious should grow out of it, will be felt when the tonnages for 1909 come to be reckoned up and compared with previous years.

The "Black Diamond," a leading organ of the United States coal trade, commences in its issue of the 10th of April a series of four articles on the "Resources and Characteristics of Canadian Consumers," written by E. B. Osborn, an English writer, who has written a volume on Canada, after close personal investigation. The first article is titled "The Garden of Canada," and is an eloquent appreciation of the wealth and possibilities of Southern Ontario. The remarks with which the editor of the "Black Diamond" prefaces the first article are of very pertinent interest to all who are interested in the development of our Canadian coal trade, and have a weighty bearing on the future prospects of the Nova Scotian. To quote: "With the changes in tariff schedules, and especially with the introduction of reciprocity, more of that coal from Pennsylvania, West Virginia and Ohio is going into the markets of Ontario and Central Canada. It is sure that Canada is awakening industrially, and that her factories and homes will be big consumers of coal before long. The wide-awake coal man will go into that field and lay his foundations for business on the rising tide of our neighbors' prosperity." The metaphor of the last sentence we have quoted may excite amusement, but the meaning of the writer is clear. To use an idiom that needs no explanation, what the writer intends to convey is that the American coal man should "get in on the ground floor." In other words, as we have previously remarked in these columns, the American is awakening to the possibilities of Canada's coal resources, and he is fully aware that unless he can introduce the product of his coal fields into Canada very shortly, the tables will be turned. As yet Canada's coal industry is in the puppy stage, and the American coal man knows it. It is a pity that Canadians are not so fully awake to the wealth of their mineral resources as are their very wide-awake neighbors below the line.

Writing on the general question of tariff laws, an editorial in the Montreal Star refers to the treatment that Canada has received in past years from the United States, and the changed attitude of our neighbors under the altering economic conditions. The Star writer does not think that this country will ever go to the lengths of the McKinley or the Dingley tariffs, and states "All that Canada will do will be to protect her own industries

from submersion and her own natural resources from depletion. And the latter part of this manifest duty she cannot take up any too soon." We think the writer of this editorial correctly interprets the feelings of every intelligent and far-sighted citizen of Canada. Our heritage is vast, but it is not exhaustless. We have not in this Dominion the almost immeasurable wealth that was once comprised in that portion of the North American continent which lies between the 45th parallel and the Isthmus of Panama, and for the sake of our posterity and the mighty nation that is arising in this Dominion of Canada, we should see to it that the shameless waste of national resources which has gone on to the south of us is not repeated here.

**Two Conciliation Boards.**—It was our duty about this time last year to detail the course of events which led up to the appointment of a Board of Conciliation to enquire into a dispute between the Provincial Workmen's Association and the workmen of the Dominion Coal Company, and to chronicle the successful settlement of the dispute through the labors of this Board, under the able chairmanship of Prof. Adam Shortt. Both sides accepted the award of the Board and a contract for two years was arranged between the two parties to the dispute. The general satisfaction which the settlement gave was shown by the numerous addresses of congratulation which were showered upon the Board, and in the Labour Gazette the Deputy Minister of Labour referred to the result as a complete vindication of the Lemieux Act and the policy of the Department of Labour. It was felt that for two years at least industrial peace was assured, and everybody felt that there was good cause for congratulation.

No sooner, however, had the award been accepted than an attempt was commenced to dissipate this general satisfaction, and a local newspaper opened its columns to a series of letters signed "Shotlighter" which stated that the workmen had been duped by their acceptance of the award, and that had the P. W. A. been a stronger and more aggressive organization much better terms might have been wrung from the Dominion Coal Company. These letters made many vague allegations, and were ingeniously calculated to foster a spirit of useless discontent with the terms of the award and more especially with the leaders of the P.W.A. who had executed the two years' agreement. There was a modicum of truth in these letters, inasmuch as the leaders of the P.W.A. had not obtained the best terms possible. Under the terms of what was known as Schedule No. 2 the Company offered their workmen higher wages than were actually granted under the award of the Board of Conciliation, but this schedule was refused by the P.W.A. leaders, who acted under instructions from their lodges. Apart from this, however, there was not the slightest justification for the attempt which was made to rouse discontent with the settlement of March, 1908. It was remarked at the time that the publication of the letters referred to served no useful purpose and would certainly result in future trouble, a prediction which events have fully justified.

It has now become known that these letters were written by persons who have since become prominent adherents of the United Mine Workers of America, and since that time this organization has been endeavoring by every means in its power to spread abroad a spirit of discontent with the present conditions at the mines in Nova Scotia, but more particularly to discredit the Provincial Workmen's Association, and to supplant it by the United Mine Workers of America. During the year just past a heated warfare, embittered by much personal feeling and spite, has been carried on between the adherents of the two rival organizations, which has resulted so far in nothing more useful than an enrichment of the members of the local legal profession. Up to the end of 1908 the Dominion Coal Company were not concerned in the fratricidal warfare of the two unions, in which they would have been acting foolishly to interfere, but at the beginning of this year the

U. M. W. A. induced several subordinate officials of the Coal Company to become members of their union. In doing this they were fully aware of the rule which obtains in all reputable British corporations, namely, that no official can belong to a labor union and retain his official position. This rule is not so rigidly observed in the United States, and indeed it is a part of the constitution of the U. M. W. A. that all workers in or about a coal mine shall belong to the union, with the single exception of the manager, and the "top-boss," whoever that elegantly named individual may be.

The coal company took the ground that no official could be allowed to belong to a labor union and retain his official position, and the option of leaving the U. M. W. A. or of vacating their official position was given to those officials who had become members of that union. Several of these men refused to withdraw from the Union and they were summarily dismissed. Other men were asked to fill the places of the dismissed officials, but they refused, and in several instances large numbers of men were laid idle owing to the impossibility of getting men to fill the vacant places. This is the discrimination complained of by the U. M. W. A. and it is the essential point on which that organization has taken issue with the Coal Company.

A Board of Conciliation was appointed by the Department of Labor to enquire into this matter. Reference was made in previous correspondence to the peculiar nature of the constitution of the Board, inasmuch as one of the members was the local president of the U. M. W. A. We venture the opinion that the repetition of an appointment of this character will bring the Industrial Disputes Act into a well-deserved disrepute. The essential principle laid down by this act is the constitution of an independent and fair-minded tribunal, which shall bring the dispassionate and detached viewpoint of an uninterested third party to the consideration of a dispute between two parties. Neither of the parties to a dispute are usually capable of an unbiased view of the matter in dispute, particularly when the disagreement arises between such supposedly antagonistic forces as capital and labor. That capital and labor are antagonistic we do not admit, but it is a popular delusion that they are. It has been found in the working of the Lemieux Act that even in the most bitter disputes there have been found possibilities of conciliation, and it has also been found that the frank discussion of matters in public before a semi-judicial tribunal has allowed a much needed escape-valve, and has in many cases resulted in increased respect of the opponents for one another. Before these boards many a workman has found that his master was not half so black as he was painted, and many an employer has been compelled to respect the manner in which his workmen presented their arguments. But this desirable state of affairs can only be brought about where the Board is composed of men entirely separated from any connection or interest in the matter under discussion.

In the case of the present Board of Conciliation two members of the Board have filed a report, in which they find that the evidence placed before them did not prove any discrimination against the United Mine Workers by the Dominion Coal Company as was alleged by the U. M. W. A. in their application for the Board, and the majority report further states that under the existing contract with the Provincial Workmen's Association the coal company could not have done otherwise than refuse to recognize the U. M. W. A. The finding is in fact a complete vindication and support of the position which has been consistently maintained by the Coal Company.

Mr. MacDougall, the third member of the Board, and the local president of the U. M. W. A., has filed a minority report disagreeing with the other two members of the Board. How could it be otherwise? As president of the U. M. W. A., Mr. MacDougall could not very well pass a practical vote of censure on the actions of his own organization. In a word, the

position of Mr. MacDougall as a member of the Board of Conciliation appointed to enquire into an alleged dispute between the Dominion Coal Company, and the U. M. W. A. was not compatible with his position as the president of that Union in his district.

Mr. MacDougall's acceptance of a position on the Board is also not in consonance with the policy of his organization. At the recent convention of the United Mine Workers at Indianapolis, a resolution was passed condemning utterly the principle of the Canada Industrial Disputes Act. The resolution stated that on the advice of Canadian members of the Union the U. M. W. A. should resist with all their power any attempt at similar legislation in the United States. The Canadian brethren informed the delegates that the reports which had been sent abroad of the beneficial effects of this Act, were false and misleading. The Convention pledged itself to resist any proposed legislation based on the Lemieux Act, and expressed itself as being utterly opposed to any law which would take away from the workmen the right of strike, or which sought to impose any restrictions on the methods of calling a strike.

In the face of this resolution, the action of the Department of Labor in appointing the president of a U. M. W. A. local as a member of a Board of Conciliation under the Lemieux Act, to adjudge a situation brought about by the actions of that same union, is not without humor, especially when it is realized that the mission of this Union in Nova Scotia so far has been to attempt destroy and disrupt a Canadian organization of 30 years' standing, to injure the coal trade in no small degree, to destroy the effects of the Board of Conciliation of 1908, and to aid the American operators in obtaining possession of markets which are ours by law and by right.

#### ONTARIO.

**Cobalt.**—Mr. H. D. Simms, who has the contract for constructing the plant of the Hydraulic Compressed Air Co. at Ragged Chutes, has 310 men at work. Part of this force is being used to complete the electric power installation below the compressed air plant, while the rest are getting ready the transmission poles, and pipe line and carrying on the underground work. About half a mile of the pipe line has been welded and the right of way for the pipe and transmission lines has been cut. There are two intake shafts which will be 330 feet deep and 8½ feet in diameter. These will be cement lined. The outlet shaft distant a thousand feet from the intakes is twenty-four feet square and 298 feet deep. The difference in elevation between the collars of the intake and outlet shafts is 54 feet. The tunnel connecting the shafts will be approximately 10 feet square with enough space above the water line to hold 100,000 cubic feet of air. A small incline shaft at an angle of 45 degrees will be run from the top of the tunnel at the lower end to the outlet shaft. This will carry the air to the 20-inch main which will be cemented into the upper end of the incline shaft. The company expects to supply power in July.

Work at the Buffalo is being carried on steadily and excellent progress is being made. The underground workings are being pushed and large amounts of ore blocked out. The concentrating plant erected on the property is treating about 30 tons of ore a day and the extraction is said to be 85 per cent of the silver contents. A cyanide plant to be run in connection with the present mill has been erected and it is expected that when the plant is in operation the percentage of extraction will be naturally increased.

The Amalgamated has started work again with a small force of men.

Active development work is being carried on by the Nipissing on their different properties. About 400 feet of drifting has been done on the Kendall vein at the south end of the lake

and the vein shows up well in the shaft at a depth of 145 feet. The big vein recently discovered in the No. 64 shaft, near the Mismaming & Hudson Bay is being drifted on. The ore body appears to be in the form of a chimney and dips off to the west. The shaft will be sunk another hundred feet before much drifting is done. On the Fourth of July vein a station is being cut at the 200 foot level preparatory to stoping. The shaft on the Meyer vein is down over 80 feet and considerable development work has been done at this level. The company has never been in a better position financially and the amount of the reserves is large.

A large force of men are at work on the La Rose and a great deal of development work is being done. The finding of values between the 100 and 200 foot levels on the No. 1 vein will add considerably to the ore reserves. At the 100-foot level a large amount of drifting has been done and the vein found to be very constant. While drifting on the 200-foot level the vein was encountered and it shows good values. A raise has been started from the lower level and will be continued to the 100-foot level.

Later developments have proved that the new vein discovered on the surface near the No. 16 shaft of the O'Brien mine, is the same as is being worked from the crosscut at the 100 foot level. It has been opened up at several places on the surface and high-grade ore found at all points. This block of ore will add largely to the reserves of the mine. It is expected that the big new concentrator will be ready to start some time in June. There are a number of shafts located at some distance from the mill. Another an electric road will be put in to handle the ore for the mill. A cyanide plant will be used in conjunction with the concentrating plant and it is expected that a saving of 95 per cent. of the silver values will be effected. Electric power will be used to run the mill.

About 110 men are employed in the mine and mill of the McKinley-Darragh. During the coming summer the No. 7 shaft will probably be sunk to greater depth. The shaft on the Lake in has been sunk to a depth of 250 feet. This summer the No. 2 shaft will be put in shape and sinking will be resumed. The concentrating mill is running steadily and putting through 65 tons of ore daily.

The new shaft sunk by the La Rose on the University property is now down 105 feet, and a station will probably be cut at this level. The vein at the bottom of the shaft has split into several small stringers but the wall rock is well mineralized.

About sixteen men are working the Silver Leaf Mine. Recently while drifting toward the Foster property a small vein carrying good silver values was discovered. This new find is being developed.

The management of the Alexandria Mine, which adjoins the Bailey on the west, intend to install a diamond drill to be operated at the 170-foot level of the shaft. It is expected that the hole will cut the Bailey No. 2 vein, which lies about 60 feet to the west of the shaft. The new compressor which has been ordered will not be installed until the roads are in better shape. A new 6-inch vein of calcite was discovered on the surface on April 12th.

A contract has been let by the Bailey Mining Co. for sinking a 200-foot shaft, and 200 feet of drifting. The management also intends to let a contract for several thousand feet of diamond drilling. This property was formerly worked by the Cobalt Central under a lease which expired on April 1st. The Cobalt Central developed two good veins on the Bailey, and the latter property will undoubtedly become an independent shipper in a short time.

It is interesting to note that the workings of the Big Pete mine, of the Cobalt Central have gone through the diabase to the lower Huronian slates, and they have already encountered two strong veins in the latter formation. This will have

an important bearing on all the properties on Diabase Mountain, notably the Silver Mountain, Alexandria and the Bailey.

The Green-Meehan Mining Co. will be taken over by the Consolidated Silver Cobalt Mines Co., which has a capital of 3,000,000 shares of a par value of \$1.00. The shareholders of the Green-Meehan will receive 1,500,000 shares of the capital stock of the new company. Work will be started as soon as possible.

A diamond drill is to be installed at the Victoria Mine, adjoining the Watts property. Holes at an angle of twenty-five degrees will be bored from the 150-foot level of the No. 4 shaft.

The Silver Cross Mining Co. will issue 15,000 shares of the treasury stock to pay for the installation of the plant and to provide for future developments.

A station is being cut at the 120-foot level of the shaft at the Cochrane Mine.

A meeting was held in Buffalo on April 14th for the purpose of organizing a new company to take over eleven properties in South Lorraine. The properties to be included in the merger are known as the Hill Claim No. 7323. Eshelman claims Nos. 10234 and 9934, Eckerson claim No. 10968, Ross claims Nos. 7305, 9153 and 9154, Lapey claim No. 10612, Heling claim No. 10957, Hill claim No. 10644 and Stowe claim No. 11257. The new company will probably be known as the South Lorraine Mines, Limited, with a capitalization of 1,500,000 shares of a par value of \$1.00 each, 400,000 shares of which will remain in the treasury.

Mr. Joseph Houston, of the Right-of-Way Mine, has been appointed consulting engineer for the Nipissing Mining Co.

The United States Steel Corporation whose engineers have been testing the iron ore deposits on the west side of the Temagami Lake, have stopped their work in that locality.

The shaft of the Moosehorn Mine in James Township is now down 100 feet and will be continued to the 125 foot level, at which depth the vein will be drifted on and cross-cuts run to tap the veins which have been discovered by surface prospecting. The sinking of the shaft to the 125 foot level will be done on contract and when that is completed the work will be taken over by the company.

A plant has been ordered for the O'Brien Mine in the Miller Lake District by Mr. J. B. Woodworth, consulting engineer for Mr. M. J. O'Brien. It will consist of boilers and a six-drill Rand compressor.

Good progress is being made in the development work of the White property at Maple Mountain, situated about 30 miles to the northwest of Cobalt. This property is largely owned by the Canadian Ores Co. whose shares are largely held in England. A plant consisting of a 9-drill Rand compressor, a 12 x 16 hoist, boilers, dynamo, etc., has been installed and will probably be in operation before the end of April. A shaft has been sunk to a depth of 150 feet between two veins which show good silver values at the surface. At the 75-foot level, cross-cuts were run to tap the veins which showed up well at this depth. An open cut has been started on one of the veins and is 20 feet deep and good silver values are found. A carload of ore has been sacked ready for shipment. Active development work is being undertaken by the mines in this locality and the district is likely to have a good future before it. Good showings have been located by the Darby Mountain Mine and Le Roy Claims. A plant has been installed by the Maple Mountain Mining Co..

The plant of the Wettlaufer Mine in South Lorraine will hardly be in operation before the end of July. The cost of installation will be about \$15,000 while the camp buildings will cost an additional \$6,000. The shaft is down 40 feet on the vein which showed native silver at the surface. At the bottom of the shaft the vein is of good width and carries good values while the wall rock is also well mineralized. About \$5,000 worth of ore was taken out while sinking the shaft the first 30 feet.

A line of motor boats will be put on the Montreal River this spring to operate between Latchford and Elk Lake City. The

operating concern is the Richardson Navigation Company of Toronto. The boats will be 40 feet long, lighted by electricity and fitted up in the most commodious manner. It is expected that they will make two trips a day between the two towns.

The winter road to Gowganda is now practically impassable and the new districts will be cut off from communication with the outside world for the next few weeks. The slush on the lakes is knee deep and going in on foot is attended by considerable danger.

### BRITISH COLUMBIA.

**Boundary.**—The Greenwood Miners' Union has made application for the appointment of a Conciliation Board, to work under the Lemieux Act in adjusting some difference which they say exists between themselves and the British Columbia Copper Company. It seems that some friction has arisen in regard to the laying off of several men; there also seems to be a difference of opinion anent the proposed reduction of 10 per cent. in the wage scale. The district officers of the Miners' Union claim that no such offer was made with proper authority. If the coal strike in Southern Alberta continues, however, they will all get a chance to sit down and think the matter over, as the British Columbia Copper Company gets its coke supply from Coleman, Alberta, and already the regular supply is shut off, making it necessary to cut in on the reserve supply, which cannot possibly last more than ten days or a couple of weeks. Even if the coal strike were settled almost immediately, it would take about two weeks to get in another supply of coke, so it would seem that a short shut-down is inevitable for the Copper Company.

It is not likely that the Snowshoe mine or the Trail smelter will be affected, as the Consolidated Company is securing its coke from the Crow's Nest Pass Coal Company, who have signed a satisfactory agreement with their men. The Snowshoe shipments for the week ending April 10th amounted to 2,950 tons, which was the heaviest output for some time.

The outlook in the Grand Forks district is exceptionally good, and there is a large amount of development work going on. Quite a number of transfers have also been made during the last week or so. The Golden Eagle, on the North Fork, is getting out regular shipments of ore, having sent out 60 tons during the past week. A party of mining men have been looking over the Yankee Girl, on Hardy Mountain, which is a high-grade property. The property has not been worked for about nine years, when it was last operated by Major Leckie.

At the Granby smelter 16,420 tons of ore was treated during the week with six furnaces, two more now undergoing the enlarging process. The two furnaces that have been enlarged are giving good results, and the work of so fitting up the balance of the battery will be rushed through as soon as possible. The Granby, in addition to treating the ores of its own mines, is smelting ore from the Republic, Surprise, Lone Pine in Washington and the Golden Eagle on the North Fork of Kettle River. The ore from most of these mines runs from \$30 to \$40 per ton, with the exception of the Republic, from which some fairly rich ore has been taken, but in small quantities, comparatively speaking.

Despite the many drawbacks that the mining industry seems doomed to contend with, it is evident that the output of the Boundary mines for the present year is going to exceed that of 1903; at any rate, this has been the case so far this year, the shipments showing an increase of about 137,000 tons, or nearly 50 per cent. over the output for 1903 during the same time. The Granby, of course, while it shipped heavily, was practically the only shipper last year, and while their output has fallen off a little during the the same time this year, still the output of the Oro Denoro, Snowshoe and other mines has more than made up for this difference and the increase as well.

The citizens of Greenwood passed the bonusing arrangement with the promoters of the tunnel-tramway enterprise by a heavy majority, and as a consequence work has already been started in the way of putting in the seven-drill air compressing plant, blacksmith shop, etc., at the site of the mouth of the proposed adit, which will be on the Strathmore claim, on which seven very rich veins of gold-silver ore have been worked to some depth. It is estimated that in the first section of 6,000 feet the bore will pierce 17 high-grade veins of ore of varying width. Over 8,000 tons of ore has been shipped from this locality that has averaged over \$100 per ton, but as it has cost over \$40 per ton to mine most of this and about \$15 for freight and smelter charges, there has not been very much in it for the owners, working without co-operation, as they have been. The present movement, however, more on a basis of co-operation, will no doubt prove a benefit to all of these nascent mines, among which may be named the Strathmore, Defiance, Yellowstone, Don Pedro, Idol and Crescent. The lode in the latter claim will be cut in the vicinity of 6,000 feet into the hill at a depth of approximately 1,300 feet. The No. 1 vein of the Strathmore will be tapped 800 feet into the hill. It is expected that this consolidation will be able to reduce the cost of mining here to about \$10 per ton and haulage and treatment to \$7 or \$8 per ton, so that it will be possible for the combined organization to make a good profit on their venture. The tramway-tunnel will be made large enough to take out 10,000 tons per day, if necessary, which, of course, it will be when the shipping of Phoenix ore begins—the tunnel ever gets in that far. And the chances are good now that work has actually been commenced.

The Crescent mine has been leased by J. Finlay & Sons, who will shortly begin work. This property has already produced over \$20,000 of high-grade ore.

**Nelson District.**—Shipments have once more been resumed from the Silver King mine, 303 tons having been sent to Trail smelter last week. This property is now unwatered to the seventh level, and there are forty men at work in the mine. It is not the intention to unwater the three lower levels to the 1,000-foot level just now, but there is no doubt that if the showing warrants, the entire mine will be opened up this season.

Some activity has been shown in the Poplar Creek section during the past winter. At the mine of J. Mobbs, of Gerrard, considerable work was done, with good results. The Calumet and Hecla has been bonded by G. Merrill from the owner, Capt. Fitzsimmons, A. P. Garrett and others. Development work will be carried on at this property during the present season. Work is to be started on the Quinne property at Ferguson also on the Nettie L. There is a nice shoot of ore on the Nettie L., but as far as it has been developed it is found narrow. Better things are expected at depth. The men who had the True Fissure under lease have thrown it up, after taking out about 100 tons of ore. It seems that the royalty of 20 per cent and the development work were too great a handicap, and they could not make the venture pay as well as they had anticipated.

The Wild Horse Creek district is apt to be a lively place "digging" again soon, if indications go for anything. Over 15 applications for leases have recently been filed with the Geological Commissioner.

The zinc miners are feeling a little glum again now that it is known that the new tariff bill will carry a provision for duty of one cent per pound on zinc in ore entering the United States. This, coming after the decision of the Supreme Court that zinc would be admitted free, kind of shatters the hope of the owners of the mines who have zinc ore on hand for shipment, and which, as yet, cannot be handled by the Nelson zinc smelter.

There is a deal on, it is said, for the Alice mine, near Creston. The property was recently gone over by Ed. Ehrenberg and Wm. Bradley, of Spokane. The Creston mine and concentrator

tor have been shut down for some time, and when the property did cease operations it came as a mild surprise, as it was generally understood there was a large body of ore blocked out.

A bond has been taken on the Golden Bell, Sheep Creek district, by Eastern capitalists. There is good vein on the property, which, however, will require development.

The largest gold brick that has yet been sent in from the Egget was shipped last week, valued at \$7,000. The property is looking well.

It seems that President Sherman, of District 18, United Mine Workers, in declaring a strike, has once more acted in a manner not approved by officials above him and many of the men whom

he represents. It would now appear that a speedy settlement will be made of the matter by T. L. Lewis, president of the Workers, when he arrives on the scene.

**Vancouver.**—Over \$100,000 of the securities of the Portland Canal Mining Company have been underwritten in the East. With the funds derived from this issue the company is going to install an up-to-date power plant, consisting of boilers, air compressor, etc., an aerial tramway of approved type and concentrator that will give the best results for their ore. This equipment will cost in the neighborhood of \$75,000. The property comprises 12 claims on Glacier Creek, and tunnel work can be done advantageously.

## GENERAL MINING NEWS.

### NOVA SCOTIA.

**Halifax.**—Hon. Mr. Chisholm has introduced several amendments to the Coal Mines Regulation Act. Every cheek weigher must send to the commissioner monthly returns of all coal weighed by him. All coal sold by retail by the owner of any mine shall be weighed at the mine and every mine owner selling by retail must furnish facilities for weighing the coal so sold. The monthly returns must contain the number of tons so sold, giving separately the number of tons supplied to workmen, or for mining operations or on the coal wharves of the owner, and the number of tons supplied to persons other than such workmen.

Another section provides that every mine examiner shall, while on discharge of his duty, use a locked safety lamp.

Borings for coal by the Canadian Consolidated Coal Co. will shortly be commenced at Lower River Inhabitants, Richmond Co. The drill to be employed is the big government drill No. 6, capable of going a depth of 3,000 feet.

Gold mining seems to be on the point of a revival in Nova Scotia. A number of mines which have been abandoned for some time are being unwatered. Among those expected to start work shortly are the Eum Secum Goldfields Co., the Ponhook Mining Co., Malaga; and the Sydney Gold Mining Co.

**Sydney.**—The Dominion Iron & Steel Co.'s plant made a record output during March in two of the most important items of production, namely, blooms and billets, and also in the matter of shipments, leaving far behind all previous figures. The total shipments were 30,000 tons.

### ONTARIO.

**Cobalt.**—The power house of the Beaver Mine was burnt down on April 4th. Arrangements have been made for power from the Temiskaming and operations are again in full blast.

The plant of the Wettlaufer mine in South Lorraine is now on the property all except the boilers. The boilers are expected to arrive at Temagami any time. The plant consists of a five-horsepower compressor two 60 h.p. boilers, a 120 light dynamo and engine, pumps, drills, etc. The shaft is being put down to the 60-foot level. The vein is about 12 inches in width of smaltite and native silver.

Diamond drilling on the Pan Silver has resulted in several veins being cut. The most promising is a calcite vein, having a width of two feet, which was cut at the 60-foot level. The drill has been shifted so as to tap this vein and prove its values at a depth of 250 feet. The main shaft is to be continued to a depth of 200 feet, when a cross-cut will be driven to No. 2 vein.

The important developments on Nipissing during the month of March included the striking of ore at the 175-foot level of No. 64, the cutting of veins No. 89 and 67 from the 60-foot level at the Kendall, and the increased showing of ore in vein No. 26 below the 110-foot level.

There are 275 men and the 27 drills at work on the La Rose. This is the largest force in camp, and nearly double the number of drills in operation upon any other property.

Considerable development is being done on the Nova Scotia. The sixth or 240-foot level is being opened, and it is intended to sink another hundred feet and make a seventh level at 340 feet. The mine at present employs 124 men. Fourteen drills are running at present, all in development work.

Work in the No. 1 shaft of Chambers-Ferland has been greatly hindered owing to the water coming in from the surface. An extra pump had to be installed to cope with the water. As a result very little drifting has been done on the large vein on the 150-foot level. The north drift has been driven 42 feet, and the south drift 38 feet.

Since the discovery of the new vein in the Cobalt Lake property, carrying native silver in quantity, drifting at a depth of 135 feet has been pushed along the vein, which averages about five inches of high-grade ore.

**Elk Lake.**—The Otisse-Currie have drifted 50 feet on their big vein at the 65-foot level, and a cross-cut has been started. They propose sinking till the 150-foot level is reached and cross-cutting again at this level.

**Gowganda.**—Two hundred town lots were offered at the April sale, and 119 were sold. The 119 lots brought a total of \$18,507.40, averaging \$152.95 per lot. The tenders ranged from \$10 to \$1,010.

**Sault Ste. Marie.**—The month of March was the best for business that the Algoma Steel Company has had since the Lake Superior Corporation commenced the manufacture of steel rails in 1902. Several conditions assisted in making the output heavy. The operation of the plant has been continuous, including the blast furnaces.

### ALBERTA.

**Lethbridge.**—Lethbridge miners, on the advice of President Frank Sherman, quit work on April 1st. All the camps in district No. 18, covering Eastern British Columbia and Alberta, are affected by the strike, with the exception of the camps of the Crow's Nest Pass Coal Company at Fernie, Michel and Carbonado, the Maple Leaf Company at Bellevue, and the Canada West at Taber.

**Medicine Hat.**—One of the municipal gas wells has been sunk to a depth of 165 feet, and a flow of 3,000,000 cubic feet per day has been developed.

**Coleman.**—A scale committee consisting of seven members of the Western Coal Operators' Association and seven members of District No. 18, United Mine Workers of America, at a conference in MacLeod extending over a large portion of March, arrived at an agreement, which agreement was to be referred to the miners, and if voted favorably upon it was arranged that both sides would meet with their attorneys to draw up the enact-

ing clause and sign the agreement for two years ending March 31st, 1911.

The referendum vote of the miners showed a majority of 209 in favor of it, and at the meeting arranged for at Macleod, March 31st, for the purpose of executing the agreement, at which the attorneys of both sides were present, F. H. Sherman, President of the Miners' Union, stated that as he had meanwhile secured what he claimed was a better agreement with the Crow's Nest Pass Coal Company, Limited, he would not sign our agreement, and if we would not sign a similar agreement to that of the Crow's Nest Pass Coal Company, Limited, it was "good-day," and thereupon left the meeting. This was followed up by his calling out the men and all of the mines comprised in the Western Coal Operators' Association are now idle. The Western Coal Operators' Association consists of the following companies:

The Alberta Railway & Irrigation Company, Limited.  
The Royal Collieries, Limited.  
The Leitch Collieries, Limited. ?  
The West Canadian Collieries, Limited.  
The International Coal & Coke Company, Limited.  
The Hosmer Mines, Limited.  
The H. W. McNeill Company, Limited.  
The Bankhead Mines, Limited.  
The Hillcrest Coal & Coke Company, Limited.

which are by far the largest majority of the operators of the district, and mining in round figures over 1,500,000 out of the 2,500,000 tons mined last year. As several of the mines in the Association are new mines that have not yet begun shipments or are only beginning to, it will be seen that the Western Coal Operators' Association not only are the largest as to numbers but as to tonnage and prospective tonnage.

Attempts have been made to re-open negotiations, but the operators remain firm in their position that the agreement arrived at in Macleod and ratified by a majority of the men in a referendum vote must be signed and put into effect.

Insert in B C Ore Shipments ... 5.... ..u MOi( SHRDLU

The following are the ore shipments for the week ending April 9th, and year to date:

#### BRITISH COLUMBIA.

**Nelson.**—The Silver King has been unwatered as far as the seventh level, and 40 men are being employed. The Silver King has been worked to a depth of 1,000 feet, but it is not intended to pump out the water below the seventh level at present.

**Grand Forks.**—No. 2 furnace of the Granby smelter has been blown in. This is the second furnace which has been enlarged 25 per cent. from its former capacity. The settlement for another year of the differences between the Crow's Nest Pass Coal Company and the miners assures the Granby Company a sufficient supply of coke and coal. The smelter treatment for the present year should show a large increase over that of last year.

**Phoenix.**—The first shipment of machinery has arrived at Eholt for the new mill now under construction at the Jewel mine. The mill is being erected by a syndicate to test a slimes-treating process of separating gold from tailings. It is the invention of H. Nichols, of the Ymir mine. It is expected that the mill will be in operation by the end of May.

**Greenwood.**—The strike in the coal mines of Eastern British Columbia may seriously affect the B. C. Copper Company, which obtains its coke from Hosmer, one of the points where the miners have quit work. The company have only enough reserve coke to last ten or twelve days.

The by-law granting a bonus of \$50,000 to the Greenwood-Phoenix Underground Tramway was carried on April 7th by 114 majority. The largest vote ever polled was cast. The company carried out its promises to the electors by starting work at 8 a.m. the next morning.

**Vancouver.**—A vein of copper ore 26 feet in width has been struck in the Ikeda mine, near Jedway, on Moresby Island, Queen Charlotte Islands. On March 22nd, at a distance in the tunnel of 850 feet, and at a depth of 350 feet, a 15-foot vein was encountered. Development on the vein showed it to be still larger, and it has now reached a width of 26 feet.

A strike of magnetite ore near the mouth of Campbell River, Vancouver Island, has been made. Tests of the ore have been made by Prof. Hoffman, of Ottawa, and Mr. J. O'Sullivan, of Vancouver. The former gauged it as running 67.47 per cent. magnetite, and the latter as running 68.14. The deposit is said to be large.

#### YUKON.

**Dawson.**—Three new discoveries of importance have been made in the Klondike this winter as the result of persistent prospecting. Early in the winter a strike was made on Barker Creek; then came the discovery on the lower end of Glacier, and lately a strike has been made on Hubbard Creek. Bedrock on this last is 45 feet deep, with 4 feet of pay that is said to run from 8 to 10 cents.

## MINING NEWS OF THE WORLD.

#### GREAT BRITAIN.

The Fife Coal Company have decided to make an experiment in the provision of bathing accommodation for their workmen. A building is to be erected at the pit head and fitted with spray baths, accommodations for undressing and changing garments, and storing working clothes.

There were 14 English mining companies organized in 1908 for the purpose of exploiting the mineral wealth of Russia. The combined capital of these companies is \$18,660,000.

The Northumberland Coal Trade Conciliation Board has decided to reduce the wages of workmen by 8¼ per cent. This is the heaviest reduction since October, 1901.

#### BELGIUM.

The Belgian Chamber of Mines has, after much discussion, passed a bill limiting the number of hours of work in mines to nine hours.

#### GERMANY.

The scheme for the formation of a German steel bar syndicate has again miscarried. It had been proposed to syndicate the export trade and pay a bounty of 15s. per ton, which would be provided by a levy of so much per ton on the inland and export sales and on the individual consumption of producers.

#### UNITED STATES.

A Western Lead Ore Producers' Association has recently been formed at a conference in Salt Lake City. The association intends to bring all guns to bear to have a protective tariff against British Columbia and Mexican lead ores.

The first steps in the upbuilding of the industry that is to rival the smelter trust has been taken. A contract has been let for the excavation work, and an order for 7,000 tons of structural steel placed. The first smelter is to be erected in Tooele

ounty, Utah, and is to have an initial capacity of from 2,000 to 2,500 tons daily.

### MEXICO.

A movement is on foot for the organization of an institute of mining engineers and metallurgists for Mexico. The new society will be known as the "Institute Mexicano de Minas y Metallurgia."

A plant to demonstrate the application of the Delprat & better zinc-flotation process will be erected in Mexico City by an English company, of which H. Lawrence Read, of Australia, is the managing director.

The problem of silicious ores for the Mexican smelters is coming of much moment. The erection of cyanide mills to treat the silicious silver ores of the big camps has changed the surplus of ores of this character into a shortage, and the condition will become more acute in the future.

### PERU.

A new smelter erected by the Cerro del Pasco Company will be in commission by April 15th, and the company's monthly output of blister copper will be increased from 2,500,000 pounds to 4,000,000 pounds.

### SOUTH AFRICA.

The Johannesburg Chamber of Mines places the March production of gold from the Rand at 608,000 ounces. It compares with 565,000 ounces the output of February, and 615,000 ounces in the opening month of the year.

Twenty stamps to be installed at the West Rand Consolidated company will be the heaviest on the Witwatersrand. Each stamp will weigh 1,850 pounds, and have a duty of 12 tons per 4 hours.

### AUSTRALASIA.

The Broken Hill Proprietary Company have completed their first zinc distillation furnace, and nine more are to be erected. Suitable clay for making the retorts has been discovered in the vicinity. It is expected that eight furnaces will be in operation by the end of 1909.

In the Broken Hill labor dispute, Justice Higgins, the arbitrator, has fixed the rate of wages for unskilled labor at 8s. 7½d. and 8s. 3d. a day, respectively. Miners are to receive 10s. a day. The hours of labor are fixed at 48 a week. The arbitrator declined to interfere with the contract system, or to compel the Proprietary Company to continue work. Justice Hig-

gins' award provides for wages on the same scale as heretofore. The Proprietary Company has appealed from this decision.

The coal mines of New Zealand are again working after the recent strike. As has nearly always been the case in New Zealand, the miners came off second best.

## COMPANY NOTES.

### DOMINION STEEL DIVIDEND.

A dividend of 10½ per cent. on account of 42 per cent. of deferred payments on the preferred stock has been declared by the Dominion Iron and Steel Company, payable May 10th. The remaining arrears of dividend are to be paid in full in the course of a year. Regular dividends are to be resumed October 1st, 1909.

### EARNINGS OF LA ROSE.

Net earnings of the La Rose Consolidated for February and March averaged about \$75,000 per month. In January the earnings were \$90,000.

The present earnings of the La Rose Company are derived from new developments, without encroaching upon reserves, which are in the neighborhood of \$2,500,000.

### KERR LAKE DIVIDEND AND BONUS.

The Kerr Lake Mining Company have declared the regular dividend of 4 per cent., and an extra dividend of 2 per cent., payable June 15th, to stock of record June 1st.

### NIPISSING'S MARCH EARNINGS.

During March, Nipissing mined ore of estimated value of \$141,623, and shipped ore of estimated value of \$193,845. Important developments of the month included the striking of ore at the 175-foot level of 64, cutting veins 89 and 67 from the 60-foot level at Kendall, and increased showing of ore in vein No. 26, below the 110-foot level.

### CONIAGAS QUARTERLY DIVIDEND.

The Coniagas Mining Company has declared the regular quarterly dividend of 3 per cent., payable May 1st.

### DIVIDEND ON TRETHEWAY.

At the meeting of the Trethewey directors an interim dividend of 10 per cent. was declared, payable on May 15th to shareholders of record on May 1st. The finances of the company are said to be in excellent shape, and a statement will shortly be made to shareholders.

## STATISTICS AND RETURNS.

The shipments for the month of March as reported by the C. & N. O. Railway Commission were:—

|                            | Cars. | Pounds.   | Tons.  |
|----------------------------|-------|-----------|--------|
| Nipissing . . . . .        | 21    | 1,386,220 | 693.11 |
| La Rose . . . . .          | 14    | 932,800   | 466.40 |
| Crown Reserve . . . . .    | 8     | 452,800   | 226.40 |
| Chambers-Ferland . . . . . | 5     | 297,440   | 148.72 |
| O'Brien . . . . .          | 4     | 269,510   | 134.76 |
| Trethewey . . . . .        | 4     | 247,620   | 123.81 |
| P. & H. B. . . . .         | 4     | 226,600   | 113.30 |
| Coniagas . . . . .         | 3     | 189,300   | 94.65  |
| City of Cobalt . . . . .   | 3     | 188,492   | 94.24  |
| Kerr Lake . . . . .        | 3     | 177,985   | 89.00  |
| Right of Way . . . . .     | 3     | 181,800   | 90.90  |
| Buffalo . . . . .          | 3     | 146,080   | 73.04  |
| McKinley-Darragh . . . . . | 2     | 111,960   | 55.89  |

|                          |    |           |          |
|--------------------------|----|-----------|----------|
| Temiskaming . . . . .    | 2  | 100,000   | 50.00    |
| Peterson Lake . . . . .  | 1  | 51,400    | 25.70    |
| Nova Scotia . . . . .    | 1  | 79,420    | 39.71    |
| King Edward . . . . .    | 1  | 44,130    | 22.06    |
| Cobalt Central . . . . . | 1  | 40,000    | 20.00    |
| Totals . . . . .         | 83 | 5,123,557 | 2,561.78 |

The shipments from the camp for the first three months of 1909 were:—

|                    | Cars. | Pounds.    | Tons.    |
|--------------------|-------|------------|----------|
| January . . . . .  | 74    | 4,750,258  | 2,375.13 |
| February . . . . . | 71    | 4,207,734  | 2,103.85 |
| March . . . . .    | 83    | 5,123,557  | 2,561.78 |
| Totals . . . . .   | 228   | 14,081,549 | 7,040.76 |

## COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt camp and those from January 1, 1909, to date:—

|                      | Week ending<br>April 10. | Since<br>Jan. 1. |
|----------------------|--------------------------|------------------|
| Ore in lbs.          | Ore in lbs.              |                  |
| Crown Reserve .....  | 118,340                  | 1,539,796        |
| Cobalt Central ..... | 43,490                   | 205,245          |
| City of Cobalt ..... | 109,000                  | 688,522          |
| Kerr Lake .....      | 40,360                   | 423,442          |
| La Rose .....        | 324,540                  | 3,709,750        |
| Nipissing .....      | 128,880                  | 3,380,060        |
| O'Brien .....        | 64,170                   | 461,320          |
| Right of Way .....   | 283,000                  | 926,890          |
| Silver Queen .....   | 62,865                   | 127,865          |
| Temiskaming .....    | 120,000                  | 590,000          |

Ore shipments to April 10, 1909, are 15,664,342 pounds, or 7,832 tons. Total ore shipments for week ending April 10, 1,294,653 pounds, or 647 tons.

|                            | Week ending<br>April 17. | Since<br>Jan. 1. |
|----------------------------|--------------------------|------------------|

... OUR MOTTO ...  
Prompt Shipment, Fair Prices

Most roofings are made of only *one layer* but Amatite is made in *five layers*. The bottom layer is wool felt, the next is real Coal Tar Pitch, the third is wool felt, the fourth is pitch again, into which is embedded the fifth layer, namely, the *Mineral Surface*.

If the weather should, in the course of years, wear away the mineral surface and dispose of the layer of Pitch (which is the most

waterproof substance on earth) it would still have to penetrate a layer of felt and another layer of composition and another layer of felt before the roof would leak.

It is easy to see why Amatite lasts so long when you realize how it is made.

That mineral surface *requires no painting* or coating whatever and will take the brunt of the weather without renewal or attention or care.

Send for a sample of Amatite. It's free.

## A NEW AND IMPORTANT PUBLICATION

Of interest to all Coal Mine Operators and Mining Men generally.

# The Dominion Coal Company

An Historical and Descriptive Pamphlet of 128 pages

Fully illustrated with half-tone diagrams and maps

The descriptions of the mining methods, fire-fighting and life-saving organizations, labor conditions, transportation facilities, etc., etc., of the Dominion Coal Company's huge enterprise are well worthy the attention of both technical workers and investors.

Mr. F. W. Gray, the author of this brochure, has done his work most capably.

The book has just appeared from the press.

Its price is \$1 net.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

A partially developed Iron Pyrites Property, showing a large body of high grade ore, assaying from 40 to 52 per cent. The property is within a mile of Railway Station and a spur can be put in to mine side at a very small cost. Water power in the neighborhood can be easily utilized if desired. Shipments of ore have already been made from the property.

Further particulars may be obtained by applying to Box K. Canadian Mining Journal, Toronto.

## THE ROAD TO GOWGANDA

BY THE

CANADIAN NORTHERN ONTARIO ROUTE

is thirty miles shorter than any other. Beginning February 2nd. through sleepers leave Toronto, 5 p.m. arriving Sellwood (Moose Mountain Iron Mines) next morning. (Breakfast served on train.) From Sellwood to Gowganda is one day's sleigh ride over the company's own road; comfortable road houses are stationed at easy distances and a fast freight and passenger service has been inaugurated with all points in Canada. Inquiries invited:—

# Geological Survey

## **PUBLICATIONS**

The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects

### **MARITIME PROVINCES**

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

### **QUEBEC**

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the province north of the St. Lawrence are also available.

### **ONTARIO**

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

### **THE PRAIRIE PROVINCES**

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

### **BRITISH COLUMBIA**

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

### **YUKON**

Many of the important areas in the Yukon have been reported upon and mapped.

### **THE NORTH-WEST TERRITORIES**

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of reports and maps are sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

*Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.*

### **THE FOLLOWING REPORTS AND MAPS HAVE BEEN ISSUED DURING THE PAST YEAR**

# Ontario's Mining Lands

---

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,  
**Toronto, Canada.**

# PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

## Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement.

The price of prospecting licenses is \$5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only \$2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, \$10.00 per acre, and on lands situate less than 20 miles from such a railway, \$20.00 per acre:

Superficial products and building materials are sold \$2 and \$4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed

lands; work must be bona fide begun within two years and \$500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of \$10.00 and a rent of \$1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run,

The government has made special arrangements with Mr. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

**The Hon. Minister of Colonization, Mines and Fisheries**  
Parliament Buildings, Quebec.

## Province of Nova Scotia

**Leases for Mines of Gold, Silver  
Coal, Iron, Copper, Lead, Tin**

**AND  
PRECIOUS STONES**

*Titles given Direct from the Crown, Royalties, and Rentals Moderate*

Copies of the Mining Law and any information can be had on application to

**The Hon. Christopher Chisholm**

Commissioner Public Works and Mines, - - - HALIFAX, NOVA SCOTIA

# A Handy Reference List

We urge you to examine the books listed below with great care. Some are brand new—all are standard. We can supply any technical book in print

## Copper

### Principles of Copper Smelting

BY EDWARD D. PETERS,  
*Professor of Metallurgy, Harvard University.*  
612 pages, 6x9; cloth, \$5.00 (21s.) postpaid.

### Modern Copper Smelting

BY EDWARD D. PETERS.  
640 pages, 6x9; cloth, \$5.00 (21s.) postpaid.

### Copper Mines of the World

BY WALTER HARVEY WEED.  
376 pages, 6x9; cloth, \$4.00 (17s.) postpaid.

### Notes on Lead and Copper Smelting and Copper

#### Converting

BY HIRAM W. HIXON.  
128 pages, 6x9. \$3.00 (12 6) postpaid.

### Pyrite Smelting

BY T. A. RICKARD,  
Formerly Editor of THE ENGINEERING AND MINING JOURNAL.  
210 pages, 6x9. \$2.00 (8 6) postpaid.

### Matte Smelting

BY HERBERT LANG.  
98 pages, 6x9. \$2.00 (8 6) postpaid.

## Lead and Zinc

### The Metallurgy of Lead

BY H. O. HOFMAN  
*Professor of Metallurgy, Massachusetts Institute of Technology.*  
600 pages, 6x9. \$6.00 (26s.) postpaid.

BOOKS BY WALTER RENTON INGALLS,  
*Editor of THE ENGINEERING AND MINING JOURNAL.*

### Lead and Zinc in the United States

6x9; cloth. \$4.00 (17s.) postpaid.  
(Price subject to change)

### The Metallurgy of Zinc and Cadmium

701 pages, 6x9; cloth. \$6.00 (25s.) postpaid.

### Lead Smelting and Refining

336 pages, 6x9; cloth. \$3.00 (12 6) postpaid.

### Production and Properties of Zinc

328 pages, 6x9; cloth. \$3.00 (12 6) postpaid.

## The Manual of Fire Assaying.

BY CHAS. H. FULTON  
176 pages, 6x9, illustrated. \$2.00 (8 6) postpaid.

Immediately upon its publication the leading assayers, metallurgists and professors of the country hailed this as the best work yet issued on the subject. It substitutes exact knowledge for the rule-of-thumb.

## Ore Dressing

BY ROBERT H. RICHARDS,  
*Professor of Mining, Massachusetts Institute of Technology.*  
Two volumes. 6x9; cloth, 1250 pages. Profusely illustrated. Per set, \$10.00 (42s.) postpaid.

The standard authority on all classes of ore dressing by one of the leading mining authorities of the world.

Remember—We Sell All Books of All Publishers

# Canadian Mining Journal

SOLE AGENTS FOR CANADA.

313 Confederation Life Bldg.  
Toronto.

## Gold and Silver

### The Chemistry of Cyanide Solutions

Resulting From the Treatment of Ores.  
BY J. C. CLENELL  
164 pages, 6x9 cloth, illustrated, \$2.50 (10 6) postpaid.

### Practical Notes on the Cyanide Process

BY FRANCIS L. BOSQUI, PH. B.  
*Superintendent of the Standard Consolidated Mining Company's Cyanide Works, Bodie, Cal.*  
201 pages, 5½x9, illustrated, \$2.50 (10 6) postpaid.

### Stamp Milling of Gold Ores

BY T. A. RICKARD.  
6x9; illustrated. \$2.50 (10 6) postpaid.

### Hydrometallurgy of Silver

BY OTTOKAR HOFMANN.  
336 pages, 6x9; cloth. \$4.00 (17s.) postpaid.

## Iron and Steel

### The Manufacture and Properties of Iron and Steel

BY HARRY HUSE CAMPBELL,  
*Metallurgical Engineer for the Pennsylvania Steel Company, etc.*  
Entirely revised in 1907. 641 pages; 6x9; illustrated.  
\$5.00 (21s.) postpaid.

### The Metallurgy of Iron and Steel

BY BRADLEY STOUTON,  
*Adjunct Professor of Metallurgy, School of Mines, Columbia University.*  
Fully illustrated; 6x9. \$3.00 (12 6) postpaid.

### The Metallurgy of Steel

BY HENRY M. HOWE, A.M., S.E., L.L.D.  
9x12; fully illustrated. \$10 (42s.) postpaid.

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver; \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Minerals; or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579,039 the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 10,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke uses, and what coke gives him best satisfaction.

**Our Analyses Speak for Themselves.**

# DOMINION

# OF CANADA

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

**W. W. CORY, Deputy of the Minister of the Interior**

# IMPORTANT NOTICE

The Canadian Behrend Dry Concentration Co., Limited has changed its name to "BEHREND CONCENTRATORS, LIMITED."

The system embraces both dry and wet features and we are prepared to treat all ores.

On Graphite, Molybdenite, Chalcopryrite and other difficult ores tailings and slimes practically ALL the values can be recovered.

A completely equipped plant, including concentrators, crushers, rolls, etc. for testing purposes is located at address below.

Write us for descriptive pamphlet. Forward sample of your ore for preliminary test.

**BEHREND CONCENTRATORS, LIMITED**

48 INSPECTOR ST., MONTREAL

## UNDERWOOD

300 Underwoods are made every working day. It is the largest output of any typewriter factory in the world.

The public would not take that output, and more if they could get it, if any other typewriter would give them as good service. The Underwood is not the cheapest in price but it is the cheapest in service. If you pay less you get less—a great deal less. The typewriter is cheap that gives you the best service, no matter what it costs. In this sense the Underwood is cheap.

# PRINCIPLES OF MINING

VALUATION — ORGANIZATION — ADMINISTRATION

Copper, Gold, Lead, Silver, Tin and Zinc

By Herbert C. Hooper, E. M. 200 pages, 6x9, illustrated, \$2.50 (10/6) net postpaid Published April 1909

Under the general headings of Valuation, Organization and Administration, Mr. Hooper gives here the Principles of Mining as developed by modern science and business methods. He adds important chapters on investment from the public's standpoint and the character, training and obligations of the mining engineer. The book is important and valuable. Mr. Hooper's very wide and varied experience and his active association with a great number of mining ventures in various parts of the world, enable him to command an unusual amount of valuable data.

At the same time, besides drawing freely from his own material and experience, he has had at his disposal the results of the work of many associates.

## CONTENTS

### Valuation of Copper, Gold, Lead, Silver, Tin and Zinc Lode Mines

Determination of average metal content; sampling; assay plans; calculation of averages; percentage of errors in estimate from sampling.

#### Mine Valuation

Calculation of quantities of ore, and classification of ore in sight.

Prospective value; extension in lepth; origin and structural character of the deposit; secondary enrichment; size of deposits; development in neighboring mines; depth of exhaustion.

Recoverable percentage of the gross assay value; price of metals; cost of production.

Redemption or amortization of capital and interest.

Valuation of mines with little or no ore in sight; valuation on second-hand data; general conduct of examination; reports.

#### Development of Mines

Entry to mine; tunnels; vertical, inclined and combined shafts; location and number of shafts.

Shape and size of shafts; speed of sinking; tunnels.

Subsidiary development; stations; cross-cuts; levels; interval between levels; protection of levels; winzes and rises. Development in prospecting stage; drilling.

#### Stoping

Method of ore breaking; underhand stopes; overhand stopes; combined stope. Valuing ore in course of breaking.

#### Methods of Supporting Excavation

Timbering; filling with waste; filling with broken ore, pillars of ore; artificial pillars; caving system.

#### Mechanical Equipment

Conditions bearing on mine equipment; winding appliances; haulage equipment in shafts; lateral underground transport; transport in stopes.

Drainage; controlling factors; volume and head of water; flexibility; reliability; power conditions; mechanical efficiency; capital outlay. Systems of drainage; steam pumps; compressed-air pumps; electrical pumps; rod-driven pumps; bailing; comparative value of various systems.

Machine drilling; power transmission; compressed air vs. electricity; air drills; machine vs. hand drilling. Workshops. Improvement in equipment.

### Ratio of Output to the Mine

Determination of possible maximum; limiting factors; cost of equipment; life of the mine; mechanical efficiency of patchwork plant; overproduction of base metal; security of investment.

#### Administration

Labor efficiency; skill; intelligence; application co-ordination; contract work; labor unions; real basis of wages.

Accounts and technical data and reports; working costs; division of expenditure; inherent limitations in accuracy of working costs; working cost sheets. General technical data; labor; supplies; power; surveys; sampling and assaying. Administrative reports.

### The Amount of Risk in Mining Investments

Risk in valuation of mines; in mines as compared with other commercial enterprises.

### The Character, Training and Obligations of the Mining Engineering Profession

This book may be had from the book department.

## SUMMARY REPORT OF THE GEOLOGICAL SURVEY BRANCH OF THE DEPARTMENT OF MINES FOR THE CALENDAR YEAR—1908.

The operations of the Geological Survey for the calendar year 1908 were more than ordinarily extensive. All the provinces and territories, with the exception of Manitoba, were given special attention. The Survey itself underwent some changes in organization. New efforts were made to meet the need for more topographical work and, in most respects, the Survey has had a successful year, despite the delay in receiving appropriations.

Amongst the changes noted in the director's report is the formation of two committees. One of these, the Geological Committee, was created for the purpose of supervising carefully all geological reports and the geologic coloring of maps before printing. Whatever delay this may entail will be amply offset by increased clearness and accuracy.

The second committee, an Editing Committee for Maps, was appointed to standardize maps, settle upon scales, and examine critically all maps before they are allowed to go to the engraver.

Quite apart from the elimination of errors, the work of these committees will tend to elevate the professional standards of each number of the Survey. The desire to get a report finished often leads the geologist to hurry his material into the printer's hands before it has been sufficiently pruned. When, however, he knows that a group of his associates is empowered to correct, modify, or to reject his reports and maps, he will be by no means eager to take unnecessary chances.

This is not the only good effect that should result from the establishment of these Committees. A Committee is impersonal. The officer of the Survey, whose work is pronounced imperfect or careless, will be apt to take his medicine more cheerfully than would be possible if on one person alone devolved the task of correction. Moreover, both committees will tend to give each member of the staff a better understanding of the difficulties, discouragements and merits of his colleagues.

The director lays emphasis upon the increasing demand for economic work. "There is . . . a wide demand for the careful study of districts containing economic minerals, and this assistance the mining public can reasonably ask of the Government."

The library of the Survey is to be made more complete. Two distributing lists are to be maintained for the Survey's publications—an exchange list, on which will be placed public libraries and institutions publishing scientific reports; and a notice list of private individuals. All reports and maps issued will be sent to

addresses on the former list; to the latter, notices of all publications as they are issued, and such publications as are requested therefrom.

Cabinets of representative Canadian rocks and minerals, prepared by members of the Survey staff, have proved most acceptable to educational institutions both here and in Great Britain. With the better facilities provided by the new building this branch of the Survey's activities will be greatly expanded.

The desirability of co-operation with the various Provinces is forcibly touched upon. It is pointed out that contoured topographical maps are indispensable, not only from a geological point of view, but also from many other standpoints. The benefits are equally shared by the Dominion as a whole and by the individual Province. Provincial assistance and co-operation would enable the Survey to cover much larger areas in its season's campaign.

After alluding to certain disabilities under which officers of the Survey labor, the director expresses his unqualified opinion that the salaries paid are far too small. In the United States Geological Survey the salaries range from \$6,000 down. The majority of responsible officers receive from \$4,500 to \$3,000. This standard has been recognized as inadequate and steps are being taken to raise it. In the Canadian Survey salaries are little more than half as large as those paid to United States officials. That the position of the Canadian Survey is unsatisfactory and undignified hardly need be stated. That it cannot hope, while the present rates of remuneration are maintained, to retain the proper type of technical employee is absolutely certain. This matter has been brought to the attention of the Dominion Government time and time again. It is hard to understand what possible reason the Government can have for prolonging a condition that will very soon bring loss and discredit upon the whole country.

It is not expedient to take up many other topics touched on by the director. We cannot refrain, however, from bringing to the attention of the Minister and the Director the fact that the Eastern Provinces are still waiting for an official visit. Last year both of these gentlemen visited the mining centres of Alberta and British Columbia. A similar tour through Ontario, Quebec and the Maritime Provinces would be beneficial to the Department and to the mining industry.

The tone and contents of the Summary Report show that Director Brock is performing the duties of his office with vigour, tact, and a degree of vision that is, perhaps, remarkable. Already the Survey has been largely removed from the sphere of political influence. Its field is being widened, its standard raised, and it is becoming what it should be, a connecting link between the mining industry and the public.

## RECIPROCITY IN COAL.

To the manufacturer and to the ordinary user of fuel the cry for the removal of tariff restrictions on United States coal is seductive in the extreme. It is an easy matter to adduce fair and convincing arguments in favor of reciprocity. And one of the most cogent of these refers to the fact that the natural market for Nova Scotian coals is the Atlantic seaboard—not the St. Lawrence. Even more cogent is the statement that the collieries of British Columbia and Alberta cannot attain their proper growth until they find an open market in the Western States.

It is claimed by the advocates of reciprocity that not only would the price of coal drop immediately but that also the prices obtaining hereafter would be uniformly lower. Further it is urged that Nova Scotia could readily switch her attention to the New England market without undue present loss and with the certainty of a much larger volume of trade. It is also confidently asserted that the growing Canadian West would receive a tremendous impetus.

In all this there is much truth. It is unfortunate however, that a serious gap is apparent in the reasoning of many of reciprocity's warmest votaries. Whatever the natural markets for Canadian coal should be the fact remains that Canada has developed her eastern and western coal fields almost entirely without the possibility of seeking other than Canadian consumers. This condition was created not by Canada but by the United States. Our neighbor, realizing that sooner or later Canadian coal will be necessary to supplement its own supplies, has made tentative but very definite advances. Undoubtedly the United States desires the abolition of the tariff, both to secure in larger measure the Quebec and Ontario trade and also for the reason indicated above.

Incidentally there is remarkable unanimity in the expressed opinions of our eastern coal operators. They appear to be by no means desirous of exchanging their present markets for those of New England. It may be that they are the best judges of their own business.

Considering the question from a national point of view, we believe that Canada has much to gain by restricting the exportation of raw material. The coal mines of Alberta and British Columbia will be a greater or less source of wealth to those provinces and to the nation generally, in proportion as greater or less quantities of their product are used by Canadian enterprises. Naturally this holds true also of Nova Scotia.

As regards the specific arguments advanced by free-traders, it is not amiss to request an answer to certain questions. Two of these questions, probably the most effective, are these: Has Canada any guarantee that the reciprocity in coal would continue in force for more than a limited period? Is there any certainty that the removal of the tariff would mean a corresponding permanent reduction in the price of coal? I

also pertinent to enquire as to whether the next generation of Canadians will be losers or gainers through any step taken now.

The whole problem must be worked out, not with an eye to the most rapid development and exhaustion of our coal deposits, but in a manner that will best preserve the future greatness of Canada and the Empire.

### POINTS OF VIEW.

It is true of coal mines and iron mines that the annual net profit—when there happens to be a profit—is small indeed compared with the total cost of production. For this reason, other things being equal, it is not a matter of grave moment whether the stock of the Crow's Nest Pass Coal Company is controlled by Americans, Germans, Kurds, or Hindoos. The principal consideration is that these important collieries be developed economically and adequately. Unless radical changes are made in our tariff relations with the United States the market for Crow's Nest Pass fuels will be confined more or less to its present geographical limits. As a business venture, the profits accruing to its shareholders are not alarmingly large. Its operations, however, furnish a livelihood for more than 2,500 men, and its coke is essential to the smelting industries of Southeastern British Columbia.

Roughly, for every dollar of dividends that these collieries earn for the company's shareholders, ten or twelve dollars are spent in Canada. Thus a demand for machinery, supplies and merchandise of all kinds is created. Briefly, the benefits that Canada as a whole derives from such large mining concerns are immediately greater than the profits reaped by all the shareholders can ever be.

Our contemporary, "The Financial Post of Canada," has been scolding about United States control of Crow's Nest Pass. It has reflected with pointless wrath upon the recently appointed president. The "Post" is confounding patriotism with provincialism.

### INSPECTION OF MINES.

Our Cobalt correspondent calls attention to the need of a resident Inspector of Mines in the Cobalt district. At present Ontario employs only one Inspector. As our correspondent points out, it is impossible for that official to enforce his recommendations. Although his powers are wide it is out of the question to think that his orders will be observed by mine operators who may see him only once or twice in six months. Indeed, it is impossible for one man to cover the Province of Ontario as closely and as frequently as conditions demand. No matter what penalties may be imposed upon those who disregard the requirements of the Mines Act, it is obvious that the proper enforcement of these regulations in a district like

Cobalt requires the constant presence of a Government official.

We believe that this is a matter that should engage the immediate attention of the Ontario Bureau of Mines. The unnecessary sacrifice of human lives must not be tolerated. Lives will continue to be sacrificed unless a thorough system of inspection is inaugurated.

Inspector Corkill has proved himself a competent and trustworthy man. But far too much is expected of him. It is time that he were given a corps of assistants.

### EDITORIAL NOTES.

The Cobalt Branch of the Canadian Mining Institute has sprung into new life. A reading-room and library are to be opened for the benefit of members and visiting mining men. A complete collection of ore and rock specimens is to be displayed. The branch will be supported entirely by local subscriptions, entirely distinct from the general funds of the Institute.

Dr. Milton L. Hersey has donated \$10,000 to the Metallurgical Department of McGill University. The revenue from this sum is to be applied to the purchase of special apparatus for research work in processes. It will be remembered that Dr. Hersey recently gave a similar amount to the School of Mining, Kingston. These are examples that might well be followed by a few more Canadians.

Mexico has declared her ability to take care of herself in mining matters. There is now in process of organization a Mexican Institute of Mining and Metallurgy, a society closely resembling in constitution our own Canadian Mining Institute. Annual and monthly meetings are to be held in the Mexico City. The membership comprises three classes, namely, members, associate members and honorary members. The proceedings will be published in Spanish, but it is specially provided that any member can make a motion, present a paper, or enter into discussion in either English or Spanish. Such motions, discussions, and papers will be printed in the language in which they are submitted.

### MONEL METAL.

It is claimed for the new alloy, monel metal, produced by the International Nickel Company, that it possesses 25 per cent. greater tensile strength and 50 per cent. greater elastic limit than the best rolled steel, with the superadded quality of incorrodibility. In chemical composition it is as follows:—

Nickel—68 to 72 per cent.  
Iron—0.5 to 1.5 per cent.  
Sulphur—0.014 per cent.  
Carbon—0.073 to 0.15 per cent.  
Copper to balance.

The new alloy is silver white, takes a brilliant polish and retains it indefinitely. It is finding many uses.

# COAL MINING IN ALBERTA DURING THE YEAR 1908.

## DEVELOPMENT OF OLD MINES AND OPENING OF NEW.

The Province of Alberta is fast becoming a considerable contributor to the coal output of the Dominion. In the year 1906 her production was 811,228 tons. Last year, 1908, the output amounted to 1,845,000 tons. That this is but slight increase—10,225 tons—over the returns for 1907, is due to adverse trade conditions. The number of new mines opened and the addition to the equipment of mines already operating indicate that Alberta is preparing for largely increased activities.

The classification of output shows that bituminous coal still preponderates. The figures for the past two years stand thus:—

|                      | 1907.     | 1908.     |      |
|----------------------|-----------|-----------|------|
| Lignite . . . . .    | 639,335   | 584,334   | tons |
| Bituminous . . . . . | 939,295   | 1,011,571 | "    |
| Anthracite . . . . . | 256,115   | 249,095   | "    |
| Totals . . . . .     | 1,834,745 | 1,845,000 | "    |

coking coals. Towards the east the high-grade lignite coals are found.

A few notes as to improvements and additions to plants may now be given.

**International Coal and Coke Co., Ltd., Coleman.**—Additions have been made to the screening plant. These comprise new picking tables, conveyors, and screens. One high pressure Canadian Rand air compressor was installed and two compressed air locomotives acquired; 40 beehive ovens were added.

**Bankhead Mines, Ltd., Bankhead.**—One additional 150 h.p. Robb boiler was installed. A new unit of briquetting plant, capacity 300 tons of briquettes in 24 hours, was erected.

**Hillcrest Coal and Coke Co., Ltd., Hillcrest.**—A new boiler and power house has been erected at the foot of the tippie. Safety lamps and electric lights are now in use in the mines.

SURFACE PLANT OF BANKHEAD MINES, LTD., BANKHEAD, ALTA.

The production of coke and briquettes is as follows:—

|                                | 1907.   | 1908.   |
|--------------------------------|---------|---------|
| Coal used in coke production.. | 112,887 | 128,397 |
| Coke produced . . . . .        | 73,782  | 75,657  |
| Briquettes produced . . . . .  | 49,585  | 36,261  |

During 1908 there were 112 coal mines in operation. Of these 19 were opened during the year. Two old mines were reopened, and six mines were abandoned.

Out of the 112 operating mines, only nine are producing bituminous coal. One, Bankhead Mines, Limited, is an anthracite mine; all the rest are producing lignite. All of the nineteen new mines opened are working lignite. From the figures of production given above, it is apparent that the majority of the lignite mines are small concerns.

Coal is being mined in the south practically from the eastern to the western boundary. In the west large bituminous mines produce both steamcoals and

**H. W. McNeill Co., Ltd., Canmore.**—A complete high pressure compressed air plant and compressed air locomotives have been installed. This has reduced the number of horses necessary for underground haulage.

**Canadian American Coal and Coke Co., Ltd., Frank.**—New screens and new electric light plant have been installed at this mine.

**Galbraith Coal Co., Ltd., Lundbrek.**—Wolff safety lamps and Monobel powder have been introduced here.

**West Canadian Collieries, Ltd., Blairmore.**—At the Bellevue mine a new tippie has been erected, equipped with cross-over dump and picking tables, capable of handling one thousand tons per day. An electric light plant for lighting tippie, mine buildings, and main gangway of mine, has been installed. Wolff safety lamps are now employed, and all blasting is done by qualified shotlighters.

**Alberta Railway and Irrigation Co., Lethbridge.**—This company have added to their No. 3 plant one 125 h.p. and one 175 h.p. Robb-Mumford boilers. At their No. 3 mine two new shafts have been put down, and

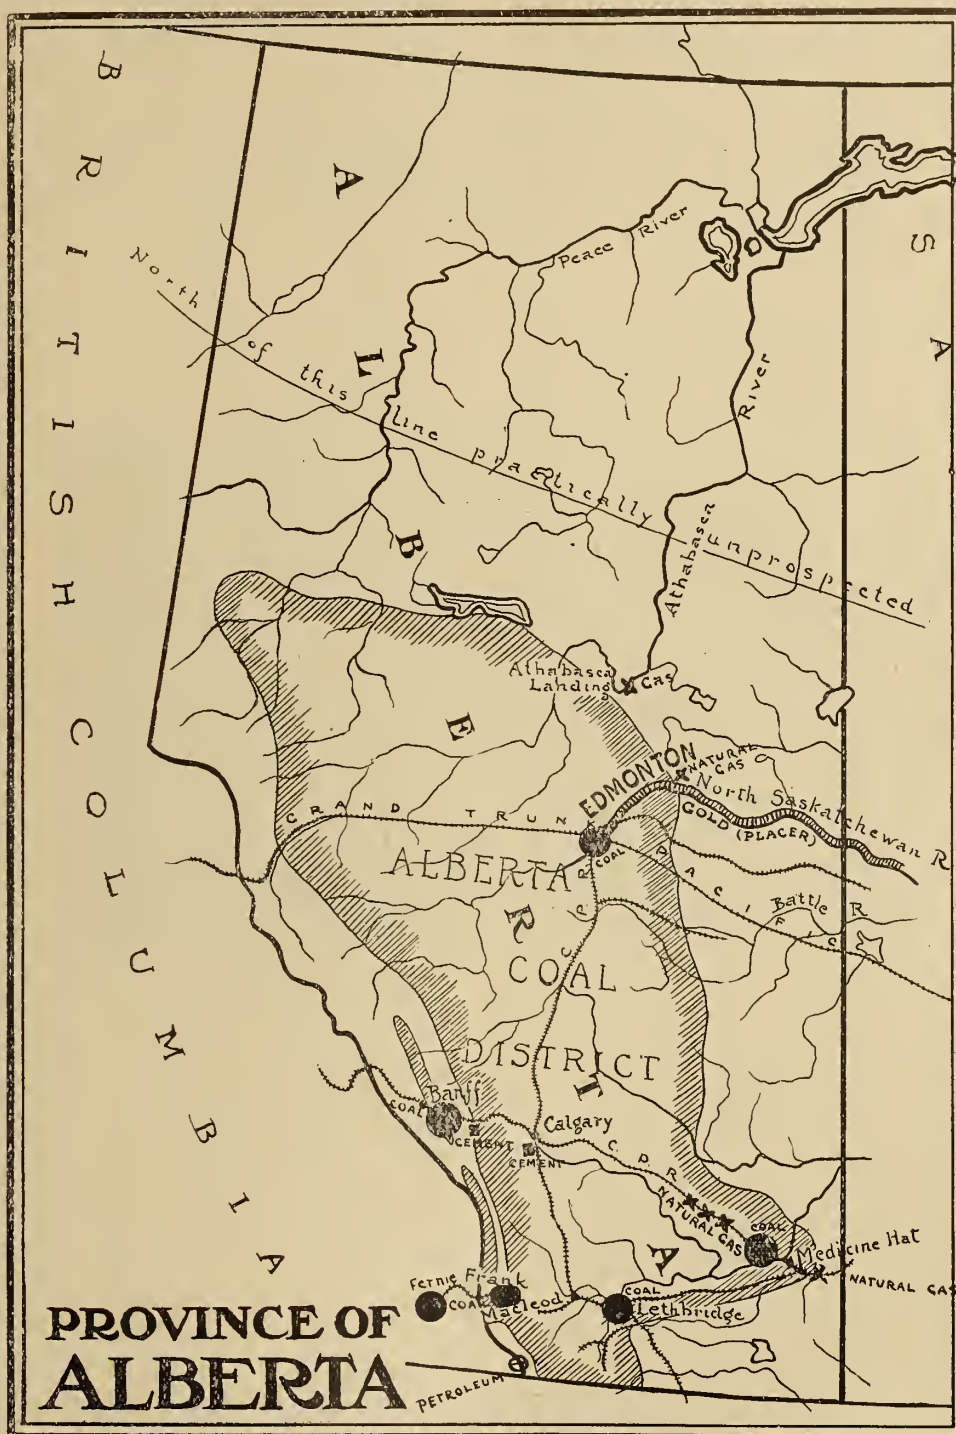

much new plant installed. A new steel tippie, capacity 1,800 tons per day, is in course of erection.

**Diamond Coal Co., Ltd., Diamond City.**—Brick buildings have been erected and, amongst other machinery, are a 275 h.p. haulage engine, three 150 h.p. Robb-Mumford boilers, a pumping station, and considerable electrical equipment. One Morgan-Gardner

compressed air punching machines. All main haulage roads and air courses have been enlarged.

**Royal Collieries, Ltd., Lethbridge.**—A branch railway now connects this colliery with Lethbridge, six miles to the south. A tippie, 400 tons per day, has been completed.

In the Edmonton district a considerable amount of

electric coal cutter and one Jeffrey electric coal cutter are in commission. The tippie is designed to handle an output of 1,000 tons per day.

**Canada West Coal Co., Ltd., Taber.**—At this mine the daily output has been increased to about 700 tons per day. Electric coal cutters have been replaced by

coal is produced for local domestic and manufacturing purposes. Most of the towns along the Canadian Northern Railway as far east as Saskatoon are supplied with fuel from these mines. Some of the larger enterprises are the following:—

**The Alberta Coal Mining Co., Ltd.,** operates at Car-

diff. The mine is equipped with a double drum Flory hoist and a first-class screening plant. The output is now about 100 tons per day. An output of 500 tons per day is aimed at.

The Cardiff Coal Company, Ltd., is one of the largest producers in the district. This company is working a lignite seam about 15 feet in thickness, lying at a depth of from 18 to 40 feet from the surface.

The Twin City Coal Company, Limited, has one of the best equipped mines in the district. A complete compressed air plant and outfit of coal cutting machines has been acquired.

The Clover Bar Coal Co., Limited, through whose property the G. T. P. has built its line, is to be worked on a large scale.

#### Accidents.

The Provincial Inspector of Mines reports less and less opposition to the introduction of safety lamps. "Some of the operators have objected to the use of safety lamps on the ground that the illumination given by the safety lamp is inferior to that given by the open light, thus causing miners to be more liable to accident,

Of a total of 62 accidents, 11 were fatal, 38 were serious, and 13 were slight. A comparison with 1907 is interesting:—

|                                                            | 1907. | 1908. |
|------------------------------------------------------------|-------|-------|

| Number of non-fatal accidents outside the mines .....      | 11    | 8     |

The absence of fatal accidents above ground, and the fact that only 11 fatalities occurred underground, are most praiseworthy. What fatal accidents did occur are thus classified:—

UNDERGROUND WORKINGS OF THE ALBERTA COAL MINING CO.'S MINE, CARDIFF, ALTA.

as with the inferior light they could not make such a thorough examination of their working places. This statement may hold true with regard to the earlier forms of safety lamps, but it is generally conceded that with the improved lamps at present on the market a sufficiently good illumination is obtained to enable the miner to make a thorough examination of his working place.

"Owing to the introduction of safety lamps the number of small burning accidents has been greatly reduced within the past two years, and in no case have we any record of there being an explosion caused by a safety lamp igniting gas in a mine."

The past year saw a considerable decrease in the number of accidents. The most serious occurred in the No. 1 mine of the H. W. McNeill Co., Ltd., where three men lost their lives in an explosion of gas from the Carey seam. The accident was due to the utter disregard of orders on the part of a certificated shotlighter, who fired a shot charged with dynamite when he had instructions to see that only, Negro Powder was used. Lax discipline is noted as one of the contributory causes.

|                              | 6                  | 32     |

The rate of fatalities below ground is 4.1 per thousand men employed, as compared with 6.30 per thousand in 1907.

BRECKENRIDGE &amp; LUND COAL CO.'S PLANT AT LUNDBRECK, ALTA.

### Prospecting.

In the remote districts of the province a large amount of prospecting has been done during the year. Throughout the prairie country a number of bore holes were put down. But the largest undertakings are carried out in the mountainous regions towards the western boundary of the province, where the German Development Company, the Kananaskis Coal Company, Limited, and the Canadian Northern Railway Company, Limited, have been active. The first-named company has had a force of men in the field all summer, and many valuable seams of coal have been opened up

on their Kananaskis, Big Horn, and Brazeau coal lands. It is reported that the C. N. R. will shortly build a line into the Brazeau coal fields. This will provide a new source of bituminous coal for railways in the north.

The Inspector, in concluding, mentions last year's visit of the Canadian Mining Institute excursion as having given wide advertisement to the mineral resources of Alberta.

The wage scale obtaining during 1908 was practically identical with that in force during 1907. The latter schedule will be found in the Canadian Mining Journal for September 1st, 1908.

## PETROLEUMS AND COALS.

Compared in Their Nature, Mode of Occurrence and Origin.

By Eugene Coste, E.M., Toronto.

(Printed as an advance paper of the Canadian Mining Institute.)

There is found in nature a great variety of compounds of carbon, not only in the sedimentary strata of all ages, but also in crystalline rocks, in igneous and volcanic rocks, in seams and veins through all these, and even in meteorites.

All these carbon-compounds have been assigned by many geologists as having the one and the same origin, namely, an organic origin from the decomposition of distillation of either animal or vegetable organic matter entombed in the strata, and they have all been grouped and classed into the one and the same series of compounds of carbon.

This organic origin cannot, of course, hold good for the natural carbon-compounds found in crystalline rocks, in igneous and volcanic rocks, in volcanic gaseous emanations, in metallic seams and veins where they are intimately associated with such minerals as quicksilver, for instance, and also when they are found in meteorites. It has, therefore, always seemed to me that this idea of only one natural series of compounds of carbon with an organic origin is so clearly at variance with so many well-known geological facts and physical laws that I cannot cease to wonder how it is possible for such a huge error to have taken the firm root it has in the science of geology. In two papers

which I read before this Institute, one nine years ago<sup>1</sup> and one six years ago,<sup>2</sup> and in another paper which I read in 1904 before the American Institute of Mining Engineers<sup>3</sup> and before the Franklin Institute,<sup>4</sup> I entered my strong protest against this fallacy. I pointed out in these papers the solfataric volcanic origin of the natural hydrocarbons or petroleum. Other geologists have also long ago given proofs of the inorganic origin of petroleum, especially Berthelot, Mendeleef, Eli De Beaumont, De Lapparent, and a number of other writers, mostly French and Russian.

But it evidently takes a long time to establish definitively even simple and palpable truths in science, as may be judged from some of the recent literature on the subject<sup>5</sup> in which the derivation of the natural hydrocarbons from organic matter is either again admitted without discussion or again sought to be proved. It appears, therefore, necessary that some of

the facts in the case be once more presented, and I have adopted in this paper the comparative form, between coals and petroleum, in the hope that it will bring out more forcibly and more clearly how entirely and absolutely different some of the natural carbon-compounds are to others in their nature, their mode of occurrence and their origin, and in the further hope that it will demonstrate that there are really two series of natural compounds of carbon, namely the organic or the coal series, or coals, and the volcanic or petroleum series, or petroleum.

### Nature.

**Coal Series.**—The coal series includes the natural carbon-compounds grading into one another from vegetation into peat, lignite, soft coal, semi-anthracite and anthracite. The exact chemical nature and proximate constitution of the members of this series are imperfectly known, and are not yet fully made out, but they are nevertheless established to be complex oxidized carbon compounds grading from definite carbo-hydrates into carbon-compounds richer and richer in carbon and poorer and poorer in oxygen as the natural carbonizing process of vegetation proceeded, the end product, anthracite, still retaining, however, some  $2\frac{1}{2}$  per cent. to 3 per cent. oxygen.

One hydrocarbon, namely, marsh gas or methane, is known to form during the natural decomposition of vegetation into coals; this is the only hydrocarbon thus formed. Many other gaseous or liquid hydrocarbons may be produced by the destructive distillation of carbonaceous matter or of coals, but these have nothing to do with the carbon-compounds formed in Nature by the normal geological processes as the destructive distillation of the sedimentary strata and of its carbonizing vegetation is not a normal geological process and never took place. This is conclusively proved by all the undistilled lignite and coal beds of the sedimentary strata all over the world and by the want of coke beds in these strata.

It may be well to point out here also that coal beds, being more or less porous strata, may and no doubt have been impregnated, in places, with gaseous and liquid petroleum, and hence these particular beds of coal, in these places, will be found really to contain natural hydrocarbons, but these are the result of a secondary enrichment by impregnation of the original coal deposit. These cases are, however, the exception, and do not in any way affect the problem, except as exceptions do, namely, to prove the rule.

**Petroleum Series.**—The petroleum series includes all the natural hydrocarbons, with the exception of marsh gas, above mentioned. These petroleum grade from natural gas into fluid crude oil or petroleum proper, into semi-fluid maltha and into viscous or solid bitumen or asphalt in their many varieties, of which such minerals as grahamite, gilsonite, elaterite, napalite, ozokerite, albertite, anthraxolite, are only a few. As the end products of this petroleum series there are good reasons, as we will see, to include both graphite and diamond, whose deposits prove that they also have had a similar inorganic origin.

A good definition of the nature of petroleum is the one of Mabery,<sup>1</sup> as follows: "Petroleum, from whatever source, is one and the same substance, capable of a simple definition—a mixture in variable proportions of a few series of hydrocarbons, the product of any particular field differing from that of any other field

only in the proportion of these series and the members of the series."

Mabery referred, I believe, in the above definition only to the crude oil or petroleum proper, but it applies equally well to natural gas, to maltha and to viscous or brittle solid asphalt; and it may be said, therefore, that all the members of the great petroleum series, as here understood and defined, are mixtures of different hydrocarbons in greater or less variety.

### Mode of Occurrence.

**Coals.**—With regard to the mode of occurrence of the members of the coal series it is only necessary for the purpose of this paper to note that they are always found in regular beds of the sedimentary strata, spreading far and wide uniformly often over hundreds and even thousands of square miles. The marsh gas of the decomposing vegetation has partly escaped into the atmosphere in the early part of the process or possibly even later, if the folding, fissuring and faulting of the coal measures have been strong, as, for instance, in the anthracite fields of Pennsylvania. What marsh gas did not thus escape, however, has not mysteriously transformed itself into the mixture of the many varieties of hydrocarbons constituting petroleum, but it is still found as marsh gas right in the coal from which it originated and where it becomes to-day the dreaded fire damp of the coal miner, often mixed with considerable choke damp or carbonic acid and with considerable nitrogen. This gaseous mixture is a very different gas from the mixture of hydrocarbons constituting natural gas; it is never, like natural gas, associated with liquid petroleum and with large quantities of very strong salt and sulphur waters, and can only be confused with it by superficial observers.

There is only one more point which I think pertinent to make here with regard to the mode of occurrence of the coals, and that is that no coal beds are found below the Carboniferous period. A small amount of coal or carbonaceous matter is, however, found in some of the Devonian shales, but this never passes into pure coal beds and fewer and fewer of these carbonaceous shales are found in the Silurian and Cambrian. The science of geology has always interpreted and explained this fact, that so little coal is found below the Carboniferous, on the undersanding that before Carboniferous time the conditions for the existence of considerable growth of vegetable matter were unfavorable, and it is a geological heresy to speak of or to believe in coal beds existing in formations lower than the Carboniferous; geology teaches us that they cannot and do not exist there. How is it then that there are so many large deposits of petroleum below the Carboniferous? It could not be, since there was so little vegetable or other organic matter entombed in these early strata, unless their origin is not in any way organic.

**Petroleum.**—If the mode of occurrence of coals is well understood, I may say by all, the mode of occurrence of petroleum certainly is not, and hence the great misunderstanding by so many about the origin of the latter. Instances are multiplying in which the natural hydrocarbons are found in emanations clearly volcanic and in igneous and volcanic rocks that is in places "where they have no business to be,"<sup>2</sup> according to those who believe in and support the organic origin of petroleum.

Still these petroleum are found often in such places, and no well-informed geologist can ignore this fact or

<sup>1</sup>Journal Am. Ch. Soc., 1906, XXVIII., p. 417.

<sup>2</sup>G. R. Mickle, Journ. Can. Min. Inst., Vol. VI., p. 123.

refuse to take account of it. Some geologists have passed such, to them, unwelcome cases over with the remark that the petroleum in the igneous or volcanic rocks were no doubt due to the distillation of the bituminous shales cut through by the intrusions; but how can a hot rock distill or drive away a vapour into itself? Some new principles in physics would have to be invented to permit of this explanation, which is simply a contradictory use of language and not a logical argument. It is also a fallacious reasoning, a reasoning in a circle, to attribute the origin of oil to bituminous shales or to shales containing oil, that is to say, to oil. In one of my previous papers<sup>1</sup> on this subject before this Institute I cited a good many instances of petroleum in volcanic emanations or in igneous or volcanic rocks, and I now refer you to this paper for full particulars of these, but I will recapitulate here what these instances prove beyond all doubt:

1st. The occurrence of graphite in igneous gneisses, granites, gabbros, pegmatite dykes, and in a quartz-porphry dyke.

2nd. The occurrences of hydrocarbons in the gaseous inclusions of the crystals of igneous rocks.

3rd. The occurrence of petroleum (liquid, semi-liquid and solid) in greenstone traps, in basalts, in trachytes, in dolorites and other volcanic rocks.

4th. The occurrence of diamond and gaseous hydrocarbons in volcanic necks and pipes.

5th. The occurrence of gaseous and liquid petroleum in the volcanic emanations of to-day.

6th. The occurrence of petroleum in freshly ejected scoriae from the volcano Vesuvius.

I will now in confirmation of the above cite a few other direct proofs of the occurrences of petroleum in crystalline rocks, in volcanic or igneous rocks or in close connection with these, and in metalliferous veins.

1st. Oil in crystalline gneiss. In Placerita Canyon, five miles east of Newhall, Los Angeles County, California, a very light oil, almost naphtha, of a gravity between 50° and 60° B., is produced from crystalline gneisses which overlay the San Gabriel granite.<sup>2</sup> It was discovered in shafting for gold. There are seven wells there, producing from depths of between 400 and 1,100 feet, one of them yielding between five and six barrels per day of oil, with 30 or 40 barrels of salt water, and another one spouted high when the oil was first struck. The crystalline schist or gneiss in which the oil occurs is micaceous and granitic, conspicuously banded and greatly contorted.

2nd. Oil and bitumen in the quicksilver deposits of California. The occurrence of petroleum in the Redington quicksilver mine, New Idria, Cal., and in the other quicksilver mines of that State, has been reported by Luther Wagoner,<sup>3</sup> Prof. Egleston,<sup>4</sup> Becker,<sup>5</sup> Prof. Christy,<sup>6</sup> and many others; it occurs abundantly as liquid oil, viscous tar, solid asphalt, and also in the gaseous state of natural gas intimately associated in the veins with the cinnabar and with metallic native mercury. Many other instances of petroleum found in quicksilver veins in Europe and in other metallic veins could be cited, in which the solfataric volcanic origin of not only the mercury or other metals, but also of the petroleum, is very apparent. The petroleum in such

deposits cannot possibly have an origin different from that of the metals themselves.

3rd. Graphite and natural gas in the metalliferous vein of Silver Islet, and graphite in the veins at Cobalt and Ducktown, Tenn. The natural gas and graphite found in abundance at the Silver Islet mine has often been cited.<sup>1</sup> Graphite was found there not only in the metalliferous vein intimately associated with rich native silver, but also in the norite or gabbro dyke accompanying the vein. At Cobalt, graphite is also found in many of the complex cobalt-nickel arsenides and silver veins.<sup>2</sup> Prof. J. F. Kemp, in his paper<sup>3</sup> on "The Deposits of Copper Ores of Ducktown, Tenn.," says "graphite or some closely related carbon-mineral is met in occasional specimens of the ore of the Mary mine. It appears to specially favor the crushed masses, and was probably of late introduction. It not only forms fine leaflike aggregates, but in this section may be detected by the microscope as minute spheroids in the midst of other minerals, such as calcite and chalcopryrite. It must have been introduced as some gaseous or very mobile liquid hydrocarbon, which has penetrated into minute cavities and filled larger cracks, and has been subsequently changed to graphite."

4th. Solid petroleum in pegmatite dykes and certain veins associated with uranium, radium and vanadium. J. Obalski, in a very interesting paper read before the 1904 meeting of this Institute,<sup>4</sup> mentioned the fact that he found in a pegmatite dyke worked for mica a radio-active carbonaceous material burning quite easily and leaving ashes containing oxide of uranium, and also that he found in the same dyke some "eleve-ite," an ore of uranium strongly radio-active and containing one-tenth of a milligram of radium. Similar so-called "coals," which are, however, solid hydrocarbons or petroleum, are found in veins in Peru,<sup>5</sup> and are mined for the vanadium they contain; these veins form lenses of "asphaltite" or solid petroleum from 0.5 inches to 22 feet wide and as much as 500 feet long, in a well-defined belt 15 miles long in the Yauli district, Peru; they are parallel and in close proximity to an obsidian intrusive dyke. In the Quespi district, Peru, there is another deposit of solid petroleum, forming also a lens-shaped mass with a maximum width of 28 feet and length of 350 feet, occupying one of the faults of a quartz porphyry dyke. Similar occurrences of hydrocarbons containing vanadium and uranium have been cited by other writers.<sup>6</sup>

5th. Graphite, diamond and hydrocarbons in meteorites. It is well known that pure carbon in the form of graphite and diamond has often been found in meteorites,<sup>7</sup> but it is not so well known that hydrocarbons have also been found in them, as cited by N. V. Sokoloff.<sup>7</sup> C. Tschermak also reports 0.85 per cent. of hydrocarbon in the meteorite which fell at Goalpara, India.<sup>7</sup>

6th. Oil and natural gas in volcanic rocks in Europe, Africa and Mexico. O. Silvestry<sup>8</sup> has found both liquid

oil and a solid paraffin in basaltic lavas near the volcano Etna. Similar occurrences have often been cited from other parts of Europe, as, for instance, in Hungary,<sup>1</sup> where liquid petroleum, asphalt and bitumen are found in rhyolite tufts, rhyolitic quartz-trachyte and andesite. On the Elansdraal farm,<sup>2</sup> Hopetown district, Cape Colony, South Africa, two dolerite intrusive sheets were traversed in a well between the depths of 121 and 137 feet, and of 364 and 401 feet, and both were found to be rich in oil in their cracks and crevices. Many other dykes and sheets of intrusive rocks in Central British South Africa are also found richly impregnated with oil.

I have myself examined similar occurrences in dolerite dykes and in calcite veins running across upper Cretaceous strata in the State of Chihuahua, Mexico.

7th. Natural gas in serpentine,<sup>3</sup> Asiatic Turkey. On the southwestern coast of Asia Minor, north of Cape Chelidonia, is the famous Chimaera, or "stone that burns," of the ancient Greeks. Here gases are continually disengaged from fissures, and are known to have been burning for at least 2,800 years, as the phenomenon was described by Hesiod before the time of Homer. According to the Russian geologist, Tschiatehaff, the gas is emitted from fissures in an altered igneous rock (serpentine), which is intrusive in limestone.

8th. The occurrence of oil around volcanic necks, Mexico. As described by Ezequiel Ordóñez,<sup>4</sup> in the State of Tamaulipas, Mexico, in the Gulf Coast lands, the oil deposits are found around vertical borings, chimneys or pipes drilled upward through undisturbed and almost horizontal shales by volcanic action during the Pliocene and perhaps Post-Pliocene times, and forming small isolated cones ranging from a few feet to four or five hundred feet in height. These cones of volcanic origin spread over the coastal peneplain, and consist either of solid basaltic lava or of basaltic tufa. At the base of these cones, or in their neighborhood, are to be found the greater number and more important seepages of oil. The Mexican Petroleum Company, at Ebano, near Tampico, have obtained their more productive wells at the base of the tufaceous cones, such as the Cerro de la Pez, where from but very few wells around this hill they have secured a daily output of 6,000 barrels. In the more highly productive wells of this company the heavy oil, abundantly charged with gas, carries a sandy material, consisting of small sharp pieces of shale, fine lapilli, and volcanic sand. The conditions above described as to the occurrence of oil prevail in an extensive zone of the Gulf-Coast lands, and extend further south in Mexico to the northern half of the State of Vera Cruz. Any number of cones, peaks and pyramids of volcanic origin are here also distributed over the coastal plain, piercing through very slightly folded or undulated strata of shales, interbedded with limestones and sandstones in thin layers, the whole probably of Upper Cretaceous age. The oil seepages are always found here also around the volcanic hills, but more frequently near the isolated volcanic peaks than in places where such peaks are closely grouped and surmounted on large bases which are composed of lava streams, preventing the oil from seeping out to the surface. Mr. Ezequiel Ordóñez further says:<sup>5</sup> "In the coastal plain lying between Tampico,

Tuxpan and Papantla will be found the greater number of volcanic hills, and the more important and densely distributed oil seepages of Mexico. I shall name a few of them. Near the Laguna de Tamiahua there exists a large pool of asphaltic oil, close to the twin volcanic hills known as Los Hermanos. Not far from the Sierra de Tantima is another big dry asphaltic lagoon. On the Hacienda de Tiacolula we found two oil seepages, one on either side of the basaltic hill called Temaxcales. The large volcanic mountain near the Hacienda de Tamatoco gives birth to several exudations of oil; on the eastern side, and not very far from its base, is found one of the larger seepages, named La Chapopotera de Juan Felipe, having an extent of one-half mile. The Chapopotera de Cerro Viejo, those of the Hacienda del Chapopote and others nearer Tuxpan are also extensive and important." It is along the Laguna de Tamiahua, mentioned by Mr. Ordóñez as affording a large seepage of asphaltum oil close to the twin volcanic hills known as Los Hermanos, that S. Pearson & Son's wonderful and uncontrollable oil gusher<sup>1</sup> has since been drilled in a property known as the San Diego de la Mar, at a point on the lagoon known as Dos Bocas. The first well drilled on this property by the firm of Pearson & Son came in at 2,005 feet, with an estimated production of 5,000 barrels of oil daily. The second well came in on July 4th, 1908, at a depth of 1,824 feet, and the oil flow was so enormous that it lifted the 1.283 feet of 8-inch casing in the hole, and also the 43 feet of 11½ casing, and broke out in every direction on the outside of the casings, catching fire from the boiler and burning, it is said, for a time at the rate of 100,000 barrels of oil daily, and for 57 days before it could be put out by pumping sand and gravel into the crater formed around the well. Three weeks after the fire was put out the diameter of the crater was 400 feet, and soundings taken 30 feet from the sides showed a depth in places of 200 feet. Approximately two acres of earth dropped into the crater at one time from the sides. This crater later on became so big that the well was finally abandoned, and it is now a veritable geyser of oil, mud and water, throwing out, it was estimated on November 1st last, 14,000,000 barrels of an emulsion of oil, mud and water.

Other instances could be given here of petroleum deposits directly connected with vulcanism, but the one just cited is enough to prove that oil fields are not commonly remote from great indications of volcanic activity, as it has been contended,<sup>2</sup> and that on the contrary enormous quantities of oil are obtained in the porous sediments or tufaceous sands around volcanic necks. When the petroleum is found, however, in the igneous, volcanic or crystalline rocks themselves it is impossible to find more than small quantities, as the necessary porosity to store these products in large enough amounts to be economically valuable is, of course, wanting on account of the imperviousness of the crystalline texture of these rocks. These small quantities of hydrocarbons are nevertheless found in many regions all over the earth in whatever small cavities, cracks and seams are co-existent with the crystalline texture of the igneous, volcanic and crystalline rocks, and even in microscopic inclusions inside of their crystals.

On the contrary, in the sedimentary strata of all ages some of the sediments, principally sandstones, con-

glomerates, limestones and sandy shales, are occasionally quite porous rocks, and therefore may and do form catch basins, tanks or reservoirs for gaseous or liquid petroleum forcing their way under strong pressure through the fractures, fissures, seams and joints of the strata. These reservoirs when thus filled constitute the important petroleum deposits, the commercial oil and natural gas fields. They are found indiscriminately in hundreds and hundreds of horizons in the strata of all ages, from the oldest Paleozoic to the alluvial gravels and sands of the Quaternary. The natural gas or igneous petroleum in these reservoirs is always found to have a heavy pressure, sometimes as high as 1,500 pounds to the square inch, and in this connection the most important factor to be noted is that this pressure in each particular field with the depth of the porous reservoir or sand containing the petroleum, indicating that its source is from below. It has been proven<sup>1</sup> beyond a doubt that this pressure is not a descending artesian or hydrostatic water pressure, the main proof being the uniformly decreasing pressure of the gas as it is being taken out; nor is it a pressure exerted by the weight of the superincumbent strata, since the gas is in the pores of firm coherent rocks not under crush. The origin of this pressure requires no explanation, and becomes self-evident when the true volcanic origin of the petroleum is understood.

Far from forming, like the coals, uniform beds spreading out uninterruptedly in every direction over wide regions, the petroleum reservoirs, on the contrary, are always found to form comparatively small, local, accidental and irregular pockets, pools or fields. In these pools or fields themselves extreme irregularity is often the characteristic of the reservoirs; patches and strips of barren and productive territory being intermixed in most intricate manners, leading often to productive wells being surrounded by dry holes, and vice versa. In many of these fields the oil and gas are obtained in a number of different sands or reservoirs, some of which are hundreds and thousands of feet lower than the upper one, and again in that respect in some of the fields there is great irregularity as to what depth the producing reservoir will be found; in neighboring wells the oil or gas may be tapped at entirely different depths. To any keen observer the above features at once indicate absolutely that the petroleum in all of their reservoirs are wanderers, not in their original home, and that all their deposits are deposits of secondary impregnation. This adventitious character of the petroleum in all their deposits is a self-evident proposition when the ever-present strong pressure of their natural gas is remembered. Fluids so elusive, ready to gush out with such force the moment the drill pierces their reservoirs, and evidently ever impelled upward through disturbed, faulted and fractured strata by the strong pressure of their gas, can never be in their original home, and the evidence that they are not is most abundant.

But there is another most important feature of the oil and gas fields, and that is they are generally very much elongated in one direction, and the different fields or pools of the same district are always arranged in lines along folded and fissured zones or belts parallel to the tectonic structure or to the orogenic uplifts of the region. The maps of the Appalachian oil and gas fields and of the Northwestern Ohio oil and gas fields published by the respective Geological Surveys of these

demonstrate that these fields form two parallel oil and gas belts to the Appalachian range of mountains, each belt being several hundred miles long. Many other illustrations of this may be found in the maps of the oil and gas districts of California, Galicia, Roumania, Russia and other oil regions. The oil and gas fields in these last-mentioned countries are always found ranged in belts at the foot and on each side, respectively, of the Coast range of the Carpathian Mountains and of the Caucasus Mountains. It is most marked in Galicia and Roumania, where the Carpathian Mountains form, as is well known, a semi-circle, and the oil and gas fields also States, illustrate this last feature most eloquently, and form the same semi-circle on both sides of the mountains and along their foothills or ranges. This reminds one of the metallogenetic provinces referred to and indicated by some geologists in regard to the incoming of particular metals into the strata at various periods of the earth's history in connection with certain volcanic manifestations and intrusions of that particular period, and along the great organic uplifts of that period. De Launay, Lindgren, Spurr and others have, in several of their writings, pointed out clearly some of these metallogenetic provinces. The alignment of the petroleum fields in every region in parallel belts to the orogenic uplifts or to the tectonic fissuring of that region shows conclusively that there are also in nature "petroliferous provinces" or petroleum-bearing belts no doubt due to causes similar to those which have given us the metallogenetic provinces, namely, tectonic disturbances accompanied by volcanic emanations. As De Launay remarks in his "Science of Geology,"<sup>1</sup> "the dislocations of the earth are more and more observed to have taken place, not alone in mountainous regions, but even in regions of plains"; he also remarks that<sup>2</sup> "all the regions of the earth, probably without exception, have been subjected to dynamic movements, to which are connected igneous manifestations of internal origin." These remarks will explain how petroleum fields even at long distances from mountainous ranges and in flat plains, such as the Northwestern Ohio, Ontario, Indiana, Illinois, Texas and Louisiana fields, etc., can nevertheless be connected with the tectonic structural dislocations of this continent and to the volcanic emanations which have accompanied these structural dislocations during the different geological ages. For further proofs of the connection of oil and gas fields with the disturbances of their region, even in the States which I mentioned last, where it is not at all apparent on the surface, I refer you to the following papers, one by G. D. Harris,<sup>3</sup> on the "Geological Occurrence of Rock Salt (associated with petroleum in Louisiana and Eastern Texas;" another by H. Foster Bain,<sup>4</sup> State Geologist of Illinois, on the "Geology of Illinois Petroleum fields;" to the records of the late Edward Orton,<sup>5</sup> on the "Northwestern Ohio Fields," and to one of my previous papers<sup>6</sup> before this Institute.

In the California oil fields a most obvious connection is to be seen in most of the fields, between the occurrence of oil and the very strong and profound disturbances of the strata occasioned by the orogenic uplifts of the hills and mountains of the Coast range. Con-

trary to many other oil fields, the oil is here often found in highly disturbed and intensely crushed strata, and in many cases along well defined and prominent structural faults. I refer you to Eldridge and Arnold's most interesting bulletin<sup>1</sup> on the Santa Clara Valley, Puente Hills and Los Angeles districts of Southern California for many good proofs and examples of this. Briefly, the evidence in this bulletin shows conclusively that the oil fields follow, in narrow but long belts, the much disturbed and faulted zones at the foot of the higher mountain ranges of the Coast Range, and that the oil is found to be stored in the porous reservoirs, rocks or in the seams and joints of any and all the strata affected by these disturbances in a vertical geological scale of some 25,000 feet, including at the bottom crystalline schists and gneisses resting on granite, then a great thickness of Tertiary resting unconformably on these crystalline schists, then an upper unconformable series, partly Tertiary and partly Quaternary, called the Fernando, and finally, overlapping all, unconformable beds of the Quaternary. To go into more details, the oil is found in the Santa Clara Valley in ascending order in the following formations:—

<sup>1</sup>U.S. Geol. Surv., Bulletin No. 309.

In the crystalline schist and gneiss penetrated by the walls to a depth of 1,100 feet; above this there is a great unconformity, but the oil is still found in the following strata in ascending order:—

Lower Eocene—Topatopa quartzites, sandstones and hard shales .....about 5,500 feet thick  
Upper Eocene—Sespe red sandstones and conglomerates .....about 3,500 feet thick  
Oligocene—Vaqueros shales, limestones and sandstones .....about 3,000 feet thick  
Miocene—Modalo sandstones and shales (probably equivalent to the Monterey formation) .....about 3,500 feet thick

Here there is another distinct unconformity, but above it we still find oil in the

Miocene, Pliocene and Pleistocene—Fernando conglomerates, sandstones and arenaceous clays .....about 9,000 feet thick

Here again is another distinct unconformity, but above it we again find the oil in

Pleistocene gravel, sandstones, clays and conglomerates of variable thicknesses.

*To be continued.*

## COINAGE IN THE BRITISH EMPIRE.

(Written for the Canadian Mining Journal by J. J. Harpell.)

In the matter of coinage as in that of credit the United Kingdom, more particularly London, may rightly be regarded as the money market of the world. According to the last official returns her imports and exports of gold and silver coin and bullion for the year 1907 were as follows:

|                               | Imports.      | Exports.      |
|-------------------------------|---------------|---------------|
| British gold and silver coin. | \$41,306,000  | \$97,813,000  |
| Foreign gold and silver coin  | 64,231,000    | 41,500,000    |
| Gold and silver bullion.....  | 247,870,000   | 198,454,000   |
| Total .....                   | \$353,407,000 | \$337,767,000 |

In addition the imports of gold and silver in the ore amounted to \$15,287,000, and the exports of the same to \$100,000. The imports of gold leaf were \$597,000, of which \$5,000 was exported. From these figures it will be seen that, neglecting the amount which may have gone out of or come into the country in the shape of manufactured articles made entirely or partly of gold and silver, the United Kingdom imported some \$40,000,000 worth of these precious metals more than she exported in the year 1907.

Incidentally these figures furnish substantial proof that the mother country is not being drained of her gold and silver as some people would have us believe, who point to the very great excess of total imports of raw materials, food stuffs and manufactured goods over total exports, which excess in the same year, viz., 1907, amounted to \$640,000,000. Evidently the many ways in which this excess may be liquidated, such as by the interest on foreign investments, the earnings of the British merchant marine and the profits from international banking, insurance and other business, are more than sufficient.

Another feature of the figures given above which deserves special notice in passing is the large imports

and exports of coins of foreign countries. This is a fair indication of the cosmopolitan character of Britain's intercourse with the world both industrial and otherwise.

But the feature of the above figures that is more pertinent to the subject of this article is that much of the precious metals comes into the United Kingdom in the form of bullion and goes out in the form of British coin, in which form the greater part of that remaining in the country is also to be found. And it is with the British minting system that I desire to deal more particularly. The figures given above pertain only to the United Kingdom. But in dealing with the manufacture of coin a general reference will be made to minting in the colonies and dependencies as well as a more or less full account of the operations as they are carried on at the Royal Mint in London; because the mints of the Empire form one great system, those in the colonies being more or less branches of the Royal Mint in London.

The world's production of gold in 1907 was \$414,700,000. Of this the British Empire produced \$247,350,000. During the same year the gold turned into coin by all the mints of the world amounted to \$369,170,000, as follows:

|                           |               |
|---------------------------|---------------|
| British Empire .....      | \$152,384,000 |
| United States .....       | 80,452,000    |
| France .....              | 75,652,000    |
| Germany .....             | 16,227,000    |
| All other countries ..... | 44,355,000    |

The world's production of silver in the same year was \$239,775,000, of which the British Empire produced \$38,141,000. In the same year the value of silver turned into coins was \$207,902,000, as follows:

|                           |               |
|---------------------------|---------------|
| British Empire .....      | \$101,835,000 |
| United States .....       | 13,110,000    |
| France .....              | 16,017,000    |
| Germany .....             | 20,922,000    |
| All other countries ..... | 56,018,000    |

In addition to gold and silver coins, the British Mints turned out \$2,676,848 nickel coins, \$271,265,647 copper coins, \$8,202,599 aluminium coins, together with a number of official seals and medals.

The above figures include the re-coinage of worn and mutilated coins withdrawn from circulation, which, however, is small as compared with the coinage from bullion.

The parent Mint of the British Empire is the Royal Mint of Tower Hill, London. Previous to 1810 it was housed in the Tower of London, where it had been as far back as history records. Formerly mints were numerous in England, there being as many as fifty in the reign of Edward the Confessor. In the reign of Stephen, when the right was granted to barons and ecclesiastics to mint for private profit, they became even more numerous. But their number from that period on diminished, until the right of coining in the United Kingdom was confined to the one mint, namely, the Royal Mint of London. There is another mint, however, at Birmingham, known as the Birmingham Mint, Limited, where coins are occasionally made under the supervision of the Royal Mint.

Branches of the Royal Mint have been established in a number of colonies as follows: Three in Australia, namely, at Sydney, Melbourne and Perth; two in India, namely, at Calcutta and Bombay, and one in Canada, at Ottawa.

Nominally and technically, in as much as the technical skill for each of these branches is supplied by the parent mint in London, these are branches of the Royal Mint. But in many respects they are completely under the control of the Government of the colony in which they are situated. Any profit accruing from their operation goes to the Government of the colony, which also bears any loss. Moreover, the bullion required is purchased by the government of the colony under whose jurisdiction the mint is operated.

The nominal head or master of the Royal Mint is the Chancellor of the Exchequer. The administrative head is the Deputy Master and Comptroller, who has under him—

- (1) A chief clerk, who is responsible for the receipt of bullion and the delivery of the coin.
- (2) A superintendent, whose business it is to look after the manufacture of coin.
- (3) An assayer, whose duty it is to value the bullion and determine the fineness of the coin.

In each of these departments, of course, there are many assistants and workers.

In connection with most mints, including many of those in the British colonies, there are refineries for refining the metal. But some years ago the Royal Mint, finding it more convenient and less troublesome to accept nothing but refined metal, leased its refinery to the Rothchilds, who now do about two-thirds of the gold refining in England. The balance is done by three or four other refineries, all conducted as private enterprises.

The Royal Mint is required, by Act of Parliament, to coin, free of charge, any refined gold offered it, and to deliver to him who brings such gold, sovereigns and half sovereigns at the rate of £3 17s. 10½d. per stand-

ard ounce troy, without any deduction for waste or seigniorage or charge for alloy or expense of manufacture. But the trouble and the time required for minting has shown those who have gold to coin that it is less troublesome and more profitable for them to take their bullion to the Bank of England, where they will receive sovereigns and half sovereigns at the rate of £3 17s. 9d. per ounce troy—the one and one-half pence being profit to the bank. The result is that almost all the gold coined at the mint is presented by the Bank of England. The bank, it may be explained, may suffer no loss of interest by the time required for coinage, because bank notes may have already been issued against it. However, this is generally not true, because for years the gold reserves of the Bank of England have exceeded its note issue. Thus from a point of loss or gain it makes no difference to the bank whether the gold is lying in its vaults in the form of bullion or going through the Royal Mint in the process of being made into coins. Refined gold bullion is generally in the form of bars, each weighing about 400 ounces. Standard gold is 916.6 fine.

Just here it may be of interest to refer to the manner in which the Bank of England receives and retains its gold. By the provisions of the British Banking Act, any one is entitled to demand notes from the Bank of England for standard gold, at the rate of £3 17s. 9d. per ounce. That is, the bank is forced to buy at a fixed price all the gold offered to it. Hence any gold offered in the open market, which is not bought at a premium by private interests or foreign banks, is turned over to the Bank of England. This provision has brought about two results. It has made London the gold market of the world, and it has made it impossible for the price of gold to fall below the price specified. On the other hand, any one possessing Bank of England notes may demand their equivalent from the bank, and foreign banks or financial houses desiring gold may procure Bank of England notes in exchange for securities, and then procure gold from the bank by presenting these notes for redemption. This privilege often leads to large and sudden demands upon the gold reserves of the bank, particularly in times of financial trouble in other countries, or when the balance of trade against the United Kingdom becomes so great that bills drawn upon her banks and business houses sell in foreign markets at discounts large enough to permit gold to be imported into these foreign countries at a profit. The only way the Bank of England can check such demands is by increasing her rate of discount. In other countries, such as France and Germany, the outflow of gold is generally checked by offering a premium for gold when it is likely to be exported. In other words, London is a free gold market, which fact has contributed not a little to making it the money market of the world.

Silver and bronze (the metal from which our "coppers" and pennies are made) are not received by the Royal Mint in the same way as gold. Silver bullion and the copper, tin, and zinc required to make bronze coins, are bought by the mint in open market, manufactured into coins, and kept in stock to be issued as required. From the manufacture of these coins there is a considerable profit to the Mint. With silver at its present price, there is over 100 per cent. profit in the manufacture of silver into coin. It is the duty of the Royal Mint to receive at their face value for recoinage all worn gold and silver coins that are withdrawn from circulation by the banks when they are found to be below the standard weight. In spite of the loss in this

recoinage, however, the profit from the manufacture of silver and bronze coins is so great that for years there has been a substantial net surplus, after paying all expenses and making good any loss on worn coins.

In 1907 the profits of the Royal Mint accruing from the coinage of silver and bronze amounted to about \$5,000,000. The total outlay for salaries and other expenses was about \$400,000. The loss on recoinage of gold was \$40,000, while on the recoinage of silver it was \$280,000. Thus on the whole the Royal Mint showed a net profit to the United Kingdom of considerably over \$4,000,000. The methods employed in the manufacture of gold and silver coins at the Royal Mint are as follows:

The gold is melted in graphite crucibles about ten inches in height and eight and one-half inches in diameter at the widest part. The charge is from 1,200 to 1,300 ounces of metal. The crucible is put into a furnace first and allowed to get red hot before the gold is put in, the copper being added last and a lid put on the crucible to check the loss by volatilization. The charge is completely melted in about one-half an hour, and it is then thoroughly mixed by stirring with a graphite rod. The crucible is lifted out and the contents poured into moulds. The molten gold which is of a pale green color, solidifies at once in the iron moulds, and the bars are taken out immediately. They are then trimmed, assayed, and rolled. The amount of gold smelted in an ordinary day's work at the Royal Mint is from two to two and one-half tons. Silver is

melted in a similar way, except that larger crucibles are used. These rough bars are then passed backwards and forwards between steel rollers until they are reduced to the required thickness. They are then examined by a "Tryer," who cuts out one or two blank discs from each fillet and weighs them. If the weight of the blank is slightly below the standard weight, a somewhat larger cutter is used so that the blank may be of the correct weight. If the blank is too heavy, the fillet is passed through the roller again. When the fillets are reduced to the correct thickness they are sent to the cutting room, where as many discs as the fillets will produce are cut out, and the "scissel" or waste part of the fillets is sent back to the melting-house. The discs are then sent on to the marking-room, where their edges are rolled to produce a raised rim or to impress a design on the edge. The discs are then submitted to an "annealing" or softening process, so that they may be more easily stamped. After softening they are sent to the stamping-room, where each is struck between dies surrounded by a collar, which leave the required impression on the surfaces of the coin. From the stamping-room they go into the weighing-room. Here the coins of the required standard weight are selected and packed up ready for circulation, while all those that are found to be either under or over the standard weight are sent back to the melting-room. Of course, all these processes are done by automatic machines of the latest and most improved designs.

## EXAMINATIONS UNDER THE COAL MINES ACT, PROVINCE OF ALBERTA.

**Fire Boss Examination. December 9th and 10th, 1908**

**Paper No. 1. Time Allowed, Two Hours.**

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

### **Coal Mines Act.**

1. State fully the various provisions of General Rule 8, relating to the use of explosives below ground. (25)
2. What are the regulations governing the employment of boys below ground? (15)
3. What are the requirements of the Act regarding the supply of timber to be kept at the mine? (15)
4. What are the requirements of the Act regarding signals and manholes on planes worked by machinery? (15)
5. What does the Act say regarding fences? (15)
6. State fully the provisions of the Act as to withdrawal of workmen in case of danger. (15)

### **COAL MINES ACT, PROVINCE OF ALBERTA.**

**Fire Boss Examination. December 9th and 10th, 1908**

**Paper No. 2. Time Allowed, Two Hours.**

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

### **Ventilation.**

1. What gases are found in mines, and how would you tell one gas from another? Describe each gas carefully and fully. (20)

2. Describe and give the use of each of the following instruments in coal mining: Barometer, Anemometer, Thermometer and Hygrometer. (15)

3. What is meant by "Diffusion of Gases" and what effect has this on mine ventilation? (15)

4. Explain all the accidents or causes which may make a safety lamp dangerous in the mine. Who discovered the principle of the safety lamp and what did this discovery consist of. (15)

5. What are the different methods of producing ventilation in a mine? State the different ways of ventilating the face of development work which is in advance of the air current. (15)

6. Ventilate the given plan, showing direction of air currents and marking on all stoppings, doors, air crossings, etc. (20)

### **COAL MINES ACT, PROVINCE OF ALBERTA.**

**Fire Boss Examination. December 9th and 10th, 1908**

**Paper No. 3. Time Allowed, Two Hours.**

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

### **Practical Work.**

1. Give a full account of all your experience in coal mining. (20)
2. Sketch and describe a mine or part of a mine with which you are acquainted. (20)
3. Describe with sketch how you would timber a main gangway in a 6-foot seam of coal, pitch of seam

35 degrees, gangway to be 9 feet wide and 6 feet in height from low side rail. (20)

4. An incline with a 30 degree pitch runs at right angles to a main entry. Sketch and describe how you would lay steel track at bottom of incline to connect with main entry track. Double track on main entry up to foot of incline, single track beyond, with single track up incline except for short distance at foot of incline. (20)

5. Describe in detail all the various methods of shot lighting as permitted in gaseous and non-gaseous mines. (20)

#### COAL MINES ACT, PROVINCE OF ALBERTA.

**Fire Boss Examination. December 9th and 10th, 1908**  
**Paper No. 4. Time Allowed, One Hour.**

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

##### Arithmetic.

1. Multiply four thousand nine hundred and eighty by thirty-four thousand seven hundred and eighty-two. (20)

2. Add the following numbers together: 642, 4812, 27, 34986, 347, 928, 63471, 62. (20)

3. Divide 68754 by 374. (20)

4. From 7896432 subtract 6797228. (20)

5. How many cubic feet of air would you require to produce in a mine where 200 men were employed, supposing each man required 200 cubic feet of air per minute and there was a leakage of 15,000 cubic feet between the intake and return airway before the air reached working faces? (20)

#### COAL MINES ACT, PROVINCE OF ALBERTA.

**Pit Boss Examination. December 9th and 10th, 1908**  
**Paper No. 1. Time Allowed, 1½ Hours**

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

##### Coal Mines Act.

1. State fully the provisions of General Rule 8, relating to the use of explosives below ground. (25)

2. State fully the provisions of the Act regarding the use of safety lamps. (20)

3. What are the requirements of the Act regarding manholes? (20)

4. What are the regulations governing the employment of boys about hoisting machinery? (15)

5. What does the Act say regarding the employment of females and boys in or about the workings of a mine? (20)

#### COAL MINES ACT, PROVINCE OF ALBERTA.

**Pit Boss Examination. December 9th and 10th, 1908**  
**Paper No. 2. Time Allowed, 2½ Hours.**

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

##### Ventilation.

1. Name the various occluded gases. Give their specific gravity and describe their various properties. (20)

2. Describe what you consider to be a good lamp for testing for gas. Why is it important that smaller

quantities should be detected than can be found with an ordinary safety lamp? (15)

3. An anemometer gives a reading of 24,000 cubic feet per minute in an airway 10 feet wide and 6 feet high while the water gauge reads 1.6 inches. What is the useful horsepower in the air? (15)

4. What pressure and power are expended in passing 20,000 cubic feet of air through an airway 8 feet by 10 feet and 6,000 feet long? (15)

5. Sketch and describe the water gauge. It is said that 1 inch of water gauge shows a ventilating pressure of 5.2 lbs. per square foot. How is this value determined? (15)

6. Ventilate the given plan, showing direction of air currents and marking on all stoppings, doors, air crossings, etc. (20)

#### COAL MINES ACT, PROVINCE OF ALBERTA.

**Pit Boss Examination. December 9th and 10th, 1908**  
**Paper No. 3. Time Allowed, Three Hours.**

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

##### Practical Work.

1. Sketch and describe the arrangements necessary at the top of a shaft to ensure safety while sinking. (15)

2. Sketch and describe how you would work a 7-foot seam of bituminous coal lying on a 28 degree pitch with a hard rock roof and floor. (20)

3. Sketch and describe how you would work a 7-foot seam of lignite coal, the seam lying flat and having a soft clay roof and floor. (20)

4. How do you draw timber in a mine and what appliances are necessary?

5. State the conditions that would guide you in determining the size of pillars to be left in room and pillar working. (15)

6. What methods would you adopt for supplying timber to the working face when the rooms have been driven a considerable distance up from the levels, the pitch of the seam being 45 degrees. (15)

#### COAL MINES ACT, PROVINCE OF ALBERTA.

**Pit Boss Examination. December 9th and 10th, 1908**  
**Paper No. 4. Time Allowed, Three Hours.**

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

##### Machinery.

1. What useful horsepower is expended in raising 10 tons to a height of 165 feet in half a minute? (15)

2. What is the horsepower of an engine with a 30-inch stroke, 15-inch cylinder and an average steam pressure of 60 lbs. per square inch, running at 40 revolutions per minute? (20)

3. What are the various appliances required by the Coal Mines Act in connection with the machinery and other plant at a mine? (20)

4. Calculate the size of steel rope required for a breaking strain of 100 tons. (15)

5. Give sketches showing various forms of rope capping. Say which form you prefer and why. (15)

6. Sketch and describe a good form of brake for a haulage engine. (15)

**COAL MINES ACT, PROVINCE OF ALBERTA.**

**Pit Boss Examination. December 9th and 10th, 1908**  
**Paper No. 5. Time Allowed, Three Hours.**

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

**Surveying.**

1. What experience and what amount of study have you had in connection with mine surveying? (15)
2. Describe briefly the instruments, etc., required for making a mine plan. (15)
3. How many tons of coal are there in 1 7-8 acres of a flat seam 6 feet in thickness? Take the specific gravity of the coal to be 1.30. (20)
4. Describe by what method you find the difference in level between the ends of a main gangway and also between the top and bottom of a steep slope or incline. (15)
5. Plot the following survey:
 

|          |                   |
|----------|-------------------|
| Bearing. | Distance in feet. |
| N. 47 E. | 88                |
| N. 3 W.  | 165               |
| S. 41 W. | 114               |
| N. 89 W. | 39                |

 (20)
6. Draw to scale a vertical 12-foot pulley wheel for 1½-inch rope suitable for a pit-head frame. Show the wheel in side and end elevation and also show a cross section of the wheel. (15)

**COAL MINES ACT, PROVINCE OF ALBERTA.**

**Mine Managers Examination. Dec. 9th and 10th, 1908**  
**Paper No. 1. Time Allowed, 1½ Hours.**

The value attached to each question is given in brackets. Candidates must obtain 70 per cent. of the allotted marks to pass.

**Coal Mines Act.**

1. State fully the various provisions of General Rule 8 relating to the use of explosives below ground. (25)
2. State fully the provisions of the Act regarding the use of safety lamps. (20)
3. Summarize the chief provisions of the Act to amend the Coal Mines Act for the purpose of limiting hours for work below ground, commonly called the "Eight Hours Law." When does this Act come into force? (20)
4. What are the requirements of the Act regarding machinery used in or about the mine? (10)
5. What returns and notices have to be sent to the Minister of Public Works and what returns and notices have to be sent to the Inspector of Mines under the Act? (25)

**COAL MINES ACT, PROVINCE OF ALBERTA.**

**Mine Managers Examination. Dec. 9th and 10th, 1908**  
**Paper No. 2. Time Allowed, 2½ Hours...**

The value attached to each question is given in brackets. Candidates must obtain 70 per cent. of the allotted marks to pass.

**Ventilation.**

1. What is the weight of a cubic foot of air at a temperature of 30 degrees centigrade, when the barometer reads 29 inches? (15)
2. As a mine manager, taking in charge the direction of operations at a large gaseous mine, how would you examine it to satisfy yourself that it was being worked safely and according to law? (15)

3. State your views as to causes of explosions in mines and what precautions you would adopt to prevent them. (15)

4. Show by calculations which of the following airways will pass the most air, power and length being the same in each case:

- |                     |                    |
|---------------------|--------------------|
| 1—One airway        | 10 feet by 10 feet |
| 2—One airway        | 5 feet by 20 feet  |
| 3—Two airways, each | 5 feet by 10 feet  |

5. Explain with diagrams the difference in construction of a force fan and an exhaust fan. With reference to force and exhaust fans, what style of fan is best suited in Alberta, bearing in mind climatic conditions? (15)

6. What are the advantages of splitting the air current? What determines the limit at which splitting should stop? (10)

7. Ventilate the given plan, showing direction of air currents and marking on all stoppings, doors, air crossings, etc. (15)

**COAL MINES ACT, PROVINCE OF ALBERTA.**

**Mine Managers Examination. Dec. 9th and 10th, 1908**  
**Paper No. 3. Time Allowed, Three Hours.**

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

**Practical Work.**

1. What are "bumps" as they occur in the mines of the Crow's Nest Pass? What are the causes and results of these occurrences and what remedy do you suggest for their prevention? (15)
2. What are the advantages of electric blasting? Describe the construction of the high tension and also the low tension detonator. How are detonators tested before use? (15)
3. Explain with sketches the different systems of drawing pillars which can be applied in the bituminous and lignite mines in Alberta. (15)
4. Classify the accidents liable to occur in lignite and bituminous mines and point out what remedies and precautions you propose to lessen these accidents. (15)
5. Describe with sketches the two main methods of mining coal. Give the conditions favorable to or requiring the application of each of these methods. (15)
6. To what use is electricity put in coal mines and what dangers arise from its use in mines? (10)
7. How would you proceed to replace a set of broken timbers in a main haulage road? Explain fully, going into details and taking into account the different conditions of roof, sides and floor. (15)

**COAL MINES ACT, PROVINCE OF ALBERTA.**

**Mine Managers Examination. Dec. 9th and 10th, 1908**  
**Paper No. 4. Time Allowed, Three Hours.**

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

**Machinery.**

1. Compare the advantages and disadvantages of power transmission into mines by means of compressed air, steam and electricity. (15)
2. How far would you place a pump above the water for it to work satisfactorily? State fully how you arrive at your answer. (10)
3. What is the pressure per square inch on the plunger of a pump raising water up a slope 300 yards long with a 33 1-3 per cent. grade? Neglecting fric-

tion, find the mean effective steam pressure required for this pump if the steam cylinder is 8 inches in diameter and the water cylinder 4 inches in diameter. (15)

4. What is there in water that produces incrustation in boilers? How do you proceed to clean a boiler? (15)

5. How far must a weight of 80 pounds be placed from the fulcrum of a safety valve having a diameter of 3 inches, the valve stem being 4 inches from fulcrum; the valve to blow off at 75 pounds pressure? (15)

6. What size of rope is necessary for a 400 foot shaft, hoisting with double decked cages, one car containing 25 cwt. on each deck? What are the various causes of wear on hoisting ropes? At which points does a hoisting rope wear most? What precautions would you take to ensure safety in the use of hoisting ropes? (15)

7. Find the H. P. of a duplex engine with 30-inch cylinders, 5-foot stroke, 40 revolutions per minute, with an average piston pressure of 40 pounds per square inch and an average back pressure of 5 pounds per square inch. (15)

### COAL MINES ACT, PROVINCE OF ALBERTA.

Mine Managers Examination. Dec. 9th and 10th, 1908

Paper No. 5. Time Allowed, Three Hours.

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

#### Surveying.

1. What is meant by declination and variation when speaking of the compass? (15)

2. How many tons of coal are there underlying a square field containing 8 acres, the seam being 6 feet 6 inches thick, lying at an angle of 31 degrees, the specific gravity of the coal being 1.51. (20)

3. Plot the following compass survey to a scale of 100 feet to 1 inch:

| Station. | Bearing.  | Distance in feet. |
|----------|-----------|-------------------|
| 1-2      | N. 32½ E. | 255               |
| 2-3      | N. 79 E.  | 134               |
| 3-4      | S. 61 E.  | 160               |
| 4-5      | S. 28¼ E. | 325 (20)          |

4. Two drill holes A. and B. 1000 yards apart, are put down to a coal seam. The depth of hole A. is 506 feet, the depth of hole B. is 766 feet. The surface at A. is 30 feet above the surface at B. Give the inclination of the seam, calculated in feet per hundred feet. (15)

5. On a mine plan there is shown a horizontal distance of 100 feet, and also a vertical distance of 100 feet. What is the distance measured on the pitch and what is the average pitch of the seam? (15)

6. How are the surface and underground surveys of a mine connected when the mine is operated by means of a shaft? (15)

### FLUXES FOR SILVER TAILINGS.

In electro-plating with silver, and in other technical processes in the industrial arts, there are large quantities of silver tailings and precipitates, for the proper recovering and utilization of which smelting is necessary. These by-products are of such different characters that if they were all melted together, there would result no pure material, but the mass would ball together in the crucible and form a half-melted lava-like material, in which, as far as industrial purposes

are concerned, the silver would be in a worse condition than before. In order to smelt such a mass and get therefrom a pure silver bar, there must be used a flux, for the purpose of setting free the oxide that has been formed, and permitting the metal to form a single mass.

The flux described below by a writer in the "Deutsche Metall Industrie Zeitung" has been used for a long time in establishments that smelt silver tailings and sweepings, and has given the highest satisfaction. Originally it was used in the cyanide process for the extraction of gold from auriferous ores.

This process consists essentially in grinding the ore fine and then leaching the resulting material in wooden tubs by a weak solution of potassium cyanide. The latter substance dissolves out the gold and silver in the ore; the clear solution is drawn off, and the noble metals precipitated by the addition of zinc scrap. The deposit thus formed consists of gold, silver, copper and a greater or less quantity of zinc. When dried, it is smelted with a flux, and the mass sent to the refinery.

As this flux has given good satisfaction in the process just named, experiments were made to determine whether or not it could be employed to advantage for other kinds of silver-smelting, and for other sweepings, etc., containing silver or gold. Favorable results were obtained therewith. The flux consists of 3.06 kg. of calcined soda (soda ash), 0.9 kg. of borax glass, 0.4 kg. of sand, 126 grams of fluorspar. Borax glass is to be used, not borax itself, as the latter, when heated, swells too much, and this makes trouble in smelting the silver-bearing or gold-bearing materials. Borax glass can be obtained by melting crystallized borax and sand in a graphite crucible, until all is clear, and then pouring the liquid. Any kind of sand may be used, only it must not be coarse.

The silver-bearing material is mixed with the flux, and the mixture melted in a graphite crucible. This latter must not be quite full, as the mass swells a great deal in melting. The amount of flux necessary depends on the kind of material being melted. For most such material, the flux is employed in the proportion of one thereof to two parts of the former.

Where the tailings or sweepings are all chlorides, more flux—even equal parts by weight—is necessary. Fluorspar is added to make the resulting mass more liquid. In a slag of thick consistence, such as is produced by soda-ash alone, the metal does not separate, but attaches itself to the slag, so that much thereof remains on the latter. Where, however, fluorspar is used, the slag is rendered so liquid that all the metal, once melted, falls at once to the bottom of the crucible.

Where there is much iron in the material to be smelted it must be removed by the aid of magnets. As iron has a very unfavorable effect on the process of smelting, it must in no case be allowed to remain in the material. Incidentally, this latter must be perfectly dry before being mixed with the flux. R. G.

Coals carrying as high as 5 per cent. of sulphur can be burned without particular danger from clinkers. A little steam introduced under the grate will relieve much of the trouble. Of course clinker may be due to other causes than sulphur, as any constituents of the ash that are readily fusible may produce it.

Bituminous coals lose about 35.05 per cent. of their sulphur during coking.

### MEETING OF THE COBALT BRANCH OF THE C. M. I.

The annual meeting of the Cobalt Branch of the Canadian Mining Institute was held on April 23rd. The President of the Institute, Dr. W. G. Miller, was present on special invitation.

The business of the evening was to appoint officers for the coming year. Retiring Chairman A. A. Cole was succeeded by Mr. R. W. Brigstocke. Mr. Cole was appointed secretary-treasurer, and an Executive Committee was elected comprising Messrs. Fraleck, Logan, Davis, Culbert and Bryce. The selection appears to be particularly fortunate. All of the members of the committee are active and prominent citizens of Cobalt. Mr. Fraleck is the well-known manager of the Cobalt Lake Mining Company; Mr. Logan, the local manager of the Canadian Bank of Commerce, is the leading banking man of the town; Mr. Davis is managing director of the Pontiac Mining Company and has for some years been an outstanding figure in Cobalt affairs; Mr. Culbert is manager of the O'Brien Mine; and Mr. Bryce is manager of the Cobalt Consolidated.

After the business of the evening had been transacted, Mr. Fraleck gave a talk on the outlook for mining in Ontario during 1909. Mr. Cole then read a paper which will appear in the Journal of the Canadian Mining Institute, entitled, "Sampling La Rose Mine."

On Monday, 26th April, a meeting of the Executive Committee was held. Messrs. Cole and Davis were appointed curators of the library and mineral collections. It was resolved that the committee would ask the leading mining companies for contributions towards fitting up the rooms.

It has been decided that the rooms of the Cobalt Branch will be fitted up with mineral show cases, maps, books, official reports, etc. The object is to make these rooms an accessible bureau of information for the general public, so that not only members, but also responsible outsiders, may avail themselves of the facilities there afforded.

The intention of the Branch is to have monthly meetings. The membership now numbers nearly 100, and there is every evidence of activity and interest.

The thanks of the Branch are due to Mayor H. H. Lang for his kindness in securing rooms.

### PURCHASING COAL UNDER SPECIFICATIONS.

In the year 1907 the U. S. Geological Survey was instructed to begin the testing of coal for government use. A uniform standard of specifications has now been adopted by all departments of the U. S. Government.

The advantages of this system are thus summed up:—

1. Bidders are placed on a strictly competitive basis as regards quality, as well as price. This simplifies the selection of the most desirable bid, and minimizes controversy and criticism in making awards.

2. The field for both Government and dealers is broadened, as trade names are ignored and comparatively unknown coals offered by responsible bidders may be accepted without detriment to the Government.

3. The Government is insured against the delivery of poor and dirty coal, and is saved from disputes arising from condemnation based on the usual visual inspection.

4. Experience with the old form of government control shows that it is not always expedient to reject poor coal, because of the difficulty, delay, and cost of removal. Under the present system rejectable coal may be accepted at a greatly reduced price.

5. A definite basis for the cancellation of contract is provided.

6. The constant inspection and analysis of the coal delivered furnishes a check on the practical results obtained in burning the coal.

### RHODESIAN GOLD MINES.

Records for the year 1907 show thirty operating gold mining companies in Rhodesia. A few details concerning one or two will show the character and scale of these enterprises.

The Giant Mines of Rhodesia, Limited, owns 90 claims in the Gadzema district of Mashonaland, 65 miles west of Salisbury and three-quarters of a mile from railway. The authorized capital is £250,000, in 250,000 shares of £1 each. All the shares are issued and fully paid. A 15-stamp mill, three tube mills and slimes plant have been in operation since December, 1905. During 1906-7, 53,897 tons of ore yielded £106,899 in gold, or 39s. 8 d. per ton. Dividends have been paid since 1905.

The Globe and Phoenix Gold Mining Co., Limited, owns 79 claims in the Sebakwe district, Matabeleland. The company has an authorized capital of £200,000, in 200,000 shares of £1 each, all of which are issued and fully paid. The equipment consists of a 40-stamp mill, a cyanide plant, and a slimes plant. During 1907 77,950 tons crushed yielded 39,791 oz. gold. At June 30th, 1907, ore reserves stood at 109,706 tons, averaging 11 dwts. per ton. Substantial dividends have been paid since 1900, with the exception of the year 1903.

The Gaika Gold Mining Company, Limited, holds 131 claims in the Sebakwe district. Its authorized capital is £300,000, in shares of £1; 205,007 shares are issued and fully paid; 168,000 vendors' shares were credited as fully paid. There are £50,000 six per cent. debentures. The equipment comprises a 5-stamp mill, a Huntingdon, and a Chilean mill. The gold output for 1907 was 10,890 ounces. At June 30th, 1907, ore reserves stood at 20,000 tons, carrying 13.5 dwts. per ton, and 32,670 tons of lower grade.

For the above figures we are indebted to Skinner's "Mining Manual."

### COLORADO COAL.

There were 14,523 men employed in the coal mines of Colorado in 1908. The average number of days worked by each man was 212, as compared with 258 days in 1907. The average production per man was 663 tons in 1908. In 1907 the average was 759. The average production per day per man was 3.13 tons in 1908, as compared with 2.94 tons in 1907. A majority of the mines held to the ten-hour day. The total quantity of coal produced was 9,634,973 short tons, having a spot value of \$13,586,988, a decrease of 10.71 per cent. in quantity and of 9.90 per cent. in value as compared with the previous year. 211 mining machines were used, producing 1,668,602 tons. Altogether 449,320 tons of raw coal were washed, yielding 336,123 of cleaned coal. All of this was used for coking. 61 men were killed and 115 injured. By far the larger number of deaths and injuries resulted from falls of roof in rooms.

## EXCHANGES.

**The Colliery Guardian, April 23, 1909.**—The Mining Department of the University of Birmingham is the subject of an article in this issue. In connection with the mining branch of this institution there is a well-equipped experimental mine. Here students are instructed in mining, ventilation, the use of explosives, rescue work, and mine surveying. The instruction offered in rescue work is particularly important. This, we believe, is the first instance of a university affording such facilities.

**The Mining Journal, April 17, 1909.**—The Royal Commission on Mines has recently issued an interim report detailing the results of an enquiry into the ventilation of collieries. "Statistics show," says the Mining Journal, "that the control exercised is more effective in the case of mines under the Coal Acts than under the Metalliferous Mines Acts, which makes us greatly regret that more attention has not been given in the proceedings of the Commission to the latter class of workings."

**Mining and Scientific Press, April 24, 1909.**—A correspondent discussing Dr. Kemp's definition of an ore suggests some modifications. As limiting the commercial phase of Dr. Kemp's definition, he cites the case of a pile of magnetite purchased at a bankrupt sale. "In a scientific sense an 'ore' is a metalliferous mineral belonging to the group of those that have commercially yielded the metals to the world's wealth. In its technical sense an 'ore' is a metalliferous mineral or an aggregate of metalliferous minerals, more or less mixed with gangue, and capable of being won as a commercial operation, adding in any way to the world's wealth." The last phrase is hardly clear enough, but it touches nearer the truth than anything we have seen.

**The South African Mining Journal, March 27, 1909.**—Public opinion on this side of the globe does not enforce upon mining companies the regular publication of monthly or even quarterly reports. The South African Mining Journal contrasts this state of affairs with that obtaining on the Rand, where every company files a return each month with the Transvaal Chamber of Mines. These are broadcast. The returns give full particulars of the month's work. Moreover, most mines cable summarized returns to London each month. Further information is given in quarterly reports, and in the event of any very important discovery being made, reserve shares being disposed of, or any large additions to plant being agreed on, interim reports are invariably issued both in Johannesburg and London. These various channels of information, along with the annual reports and speeches and discussions at the annual meeting, leave little to be desired.

**The Iron and Coal Trades Review, April 23, 1909.**—Under the heading, "What Percentage of Firedamp is Dangerous?" the Review discusses Dr. Cadman's report on this vital point. Dr. Cadman's conclusions are that less than 1 per cent. can be discovered by a careful observer on the flame of any safety lamp burning pure colza, by the aid of a magnifying glass; that 2 per cent.

of firedamp gives a complete cap a quarter of an inch high; and that when the return air from a stall, panel, or district contains 2 per cent. of gas, the mine is dangerous and the men ought to be withdrawn. It was shown that firemen and deputies have almost universally been in the habit of testing for firedamp without entirely obliterating the white light of their wick flames, and consequently percentages of 3 and 3½ have been the smallest discovered. Of 41 firemen examined it was found that 21 either had no nystagmus or were very slightly affected, seven were slightly affected, six were distinctly affected, and seven were severely affected.

**The Engineering and Mining Journal, May 1st, 1909.**—In an interesting article on Gow Ganda, Mr. H. E. West concludes that in the Miller Lake and Gow Ganda districts are many favorable prospects that promise to become mines. "At the same time it is certain that not one of these embryonic mines can become a steady producer of silver without the assistance of the railroad. It would, therefore, seem to be the duty of the Government to provide the means whereby these latent assets can be quickened into life, and increase the silver production of Ontario.

Mr. West indicates that, whilst it is within the realm of possibility that the whole Montreal River section may, within five years, equal the present production of Cobalt, this must be based upon the two assumptions that railroad construction is commenced forthwith and that the development of the mines at depth prove not less favorable than at the surface.

These assumptions, we suggest, should have been reversed in order.

### PERSONAL AND GENERAL.

Mr. D. H. Browne, chief metallurgist to the Canadian Copper Company, was in Toronto on April 29th.

Mr. John B. Hobson has returned to Victoria, B.C., after having spent the winter in California. He will shortly leave for Cariboo.

Mr. Benj. B. Lawrence, consulting engineer for the Kerr Lake Mining Co., Cobalt, Ont., has returned to New York from a visit to the property.

Capt. W. H. Jeffery, superintendent of the Chambers-Ferland Mine, Cobalt, has retired from that position to devote his time to his Montreal River interests.

Mr. Horace G. Nichols, manager of the Ymir mine, British Columbia, is installing his new slimes-treating process in the new stamp mill being installed at the Jewel mine.

Dr. Milton L. Hersey, of Montreal, has returned from Germany, where he went in connection with the sampling of Crown Reserve ore purchased by the German Government.

Mr. A. B. Willmott, of Sault Ste. Marie, was recently in Toronto on his way home from North Carolina, where he had been investigating iron ore properties for some clients.

Prof. Macoun, of the Geological Survey of Canada, accompanied by Mr. C. H. Young, of Ottawa, has gone

to British Columbia to collect natural history specimens for the Victoria museum.

Mr. Chas. Watson, brother of the chief engineer of the Nipissing and La Rose Mining Companies, has been appointed engineer of the Chambers-Ferland Mining Co., in place of Capt. W. H. Jeffrey.

Dr. W. F. King, Canadian astronomer and boundary commissioner, has left Ottawa for Washington to arrange with Dr. O. H. Teddman, American boundary commissioner, for the resumption of boundary survey work.

Mr. Paul S. Couldrey, manager of the Le Roi No. 2 at Rossland, has resigned to accept a position in another field. Except for an interval spent in Western Australia, Mr. Couldrey has been in charge of the Le Roi since 1902.

Mr. R. T. Hopper, of Montreal, the president of the Standard Asbestos Co. and vice-president of the Dominion Asbestos Co., both of which are included in the merger, will join the board of the Amalgamated Asbestos Corporation.

Mr. C. H. Macmillan, formerly superintendent of the Dominion Iron & Steel Co., who has been recuperating in Maine for a year or so, has been appointed superintendent of the steel department of the company, and assumed his new duties on the first of the month.

### CORRESPONDENCE.

Editor Canadian Mining Journal, Toronto, Ont.

Dear Sir,—On receipt of your issue of April 15th we notice a criticism by Gerald Dobbs on the method of testing air pipes as suggested in an article of ours in your issue of Feb. 15, 1909.

In answer to Mr. Dobbs we beg to call his attention to the latter part of the paragraph on this subject—"Corrections for temperature will be necessary for accurate results, but in practice are not needed."

If the expansion by leakage of the air in the pipe lines can be considered as Isothermal, that is that the temperature is constant, then Mr. Dobbs figure of 7.35 instead of 10 lbs. drop is correct. On the other hand, if the expansion is Adiabatic, that is that the temperature varies, the figure will be considerably more than

this. As it is probable on pipe lines on which there is considerable loss that the expansion would be neither Isothermal or Adiabatic, we have taken 10 lbs. as a convenient figure.

1st. Because it is an approximation between Isothermal and Adiabatic.

2nd. Because it is a convenient figure for the workmen to read.

The average pressure gauge used in this work is only graduated to 5 lbs. Of course this could be overcome by placing a special graduation on the face of the dial, or by the purchasing of more elaborate gauge. Even this would require a special pressure curve to be made for whichever gauge is employed.

As mentioned in our article, we hardly think all this is worth while, as the main point is to stop the leaks, and this can be done quite as efficiently in the rough and ready manner proposed, as can be accomplished by going into the matter in great detail.

Trusting this explanation will be satisfactory to Mr. Dobbs, we remain,

Yours sincerely,

R. E. CHAMBERS,  
A. R. CHAMBERS.

### INDUSTRIAL NOTES.

A Robb-Armstrong high speed engine will be installed at the new central lighting station to be erected at Listowel, Ont.

Southern Wisconsin Power Co., Madison, Wis., has recently installed a 30-ton travelling Northern crane and a 6-ton electric mono-rail hoist, both furnished by the Northern Engineering Works of Detroit.

The Consolidated Mining and Smelting Company, at Trail, B.C., is producing a new electrolytic bearing metal, which is claimed to be equal to the highest grade friction alloys.

The San Francisco branch office and warerooms of the Sullivan Machinery Company are now located at 461 Market Street, in the Sheldon Building, instead of at 26 Fremont Street, as heretofore. Sullivan air compressors, diamond drills, rock drills, and other mining machinery are carried in stock at this office.

## NEW MINING AND METALLURGICAL PATENTS.

No. 115,938. Mine Door.—Joseph L. Dinwiddie and Albert F. Braun, both of Carlinville, Illinois, U.S.A., 5th January, 1909; 6 years. Filed 12th September, 1908. Receipt No. 162,417.

Claim.—In an apparatus for the purpose stated the combination with a hinged door and a railway track, of a door operating member arranged adjacent to one of the rails of said track and having its upper edge normally above said track rail, said member being provided with a series of granulated slots, a trip, a trip bar, said bar having a series of granulated slots, rock arms supporting said members and trip bar and engaging said slots, operative means for said door and connection between said member and said door operative means.

**No. 115,989. Pulverizing Mill.**—George E. Rudnick, Iola, Kansas, U.S.A., 5th January, 1909; 6 years. Filed 25th November, 1908. Receipt No. 164,437.

Claim.—In a pulverizing mill the combination with a base constituting a basin, a die ring within the basin, and a cylindrical screen surrounding and upstanding from the ring, of a revoluble bearing sleeve, means for supporting the same above the basin, a driving element

*Fig. 1.*

connected thereto, a skirt depending from the sleeve, boxes mounted to oscillate within and rotate with the driving element, shafts journaled within and depending from said boxes, said shafts being free to oscillate within the sleeve and skirt, boxes surrounding the shafts and bearing within the skirt, grinding rollers carried by the shafts and disposed to co-operate with the die ring.

**No. 116,019. Steel Manufacture.**—The Pearlite Steel Company, Limited, assignee of Andrew Charles Joseph Charlier, both of London, England, 12th January, 1909; 6 years. Filed 13th July, 1908. Receipt No. 160,652.

Claim.—1. A process for the treatment of low grade steel consisting in immersing the heated metal in a bath into which hydrogen is introduced or in which hydrogen is evolved and reheating the metal after removal from the bath, substantially as hereinbefore described.

2. A process for treating low grade steel consisting in immersing the heated metal in a chilling or fixing bath containing or evolving hydrogen gas which under the action of the constituents of the bath unites with the carbon and iron of the metal to form hydro-carbide of iron, and in reheating the metal after removal from the bath, substantially as hereinbefore described.

3. High grade steel manufactured from low grade steel by the process substantially as hereinbefore described.

**No. 116,043. Silver Precipitating System.**—Frank W. Pugsley, Cobalt, Ontario, Canada, 12th January, 1909; 6 years. Filed 19th October, 1908. Receipt No. 163,344.

Claim.—1. The herein described process for precipitating silver from thiosulphate solution either calcium or sodium consisting of adding to the solution metallic aluminum in the presence of a fixed alkali, as set forth.

2. The herein described process for precipitating silver from a thiosulphate solution either calcium or sodium, consisting of first filtering the solution and then adding to the solution metallic aluminum in the presence of a free fixed alkali, as set forth.

**No. 116,057. Rock Drill.**—James S. Harlow, Mineral, Virginia, U.S.A., 12th January, 1909; 6 years. Filed 24th August, 1908. Receipt No. 161,887.

Claim.—A rock drill operating device consisting of a cylinder having suitable ports, a piston therein having shoulders, a tappet to be engaged by the shoulders, a sliding valve controlling ports leading to the cylinder

operated by the tappet, a lever pivoted to the tappet, and means for adjusting the end of the lever into and out of the path of travel of the shoulders of the piston.

**No. 116,066. Rock Drill.**—William Charles Stephens, Carn Brea, Cornwall, England, 12th January, 1909; 6 years. Filed 31st October, 1908. Receipt No. 163,710.

Claim.—1. In a percussive rock drill of the hammer type and wherein the feed motion is automatically effected by air pressure, the arrangement of the feed

cylinder and hammer cylinder side-by-side and parallel with each other for the purpose of shortening the drill, substantially as described.

No. 116,182. Alloy.—Enrique A. Touceda, Albany, New York, U.S.A., 19th January, 1909; 6 years. Filed 7th November, 1908. Receipt No. 163,933.

Claim.—1. A bearing composed of an alloy of lead and cadmium.

2. A bearing composed of an alloy composed of lead and cadmium in which the lead predominates.

3. A bearing composed of an alloy one of whose ingredients is lead toughened and hardened by the presence of cadmium.

4. A bearing composed of an alloy of lead and other metals, said alloy being hardened and toughened by the presence of cadmium.

5. A bearing metal composed of an alloy whose base

is lead hardened and toughened by the presence of cadmium.

## INDUSTRIAL NOTES.

**Sullivan Air Compressors—Booklet No. 106—The Sullivan Machinery Co., Railway Exchange, Chicago, U.S.A.**

We have just received booklet No. 106 describing Sullivan air compressors. The booklet is not a complete catalogue, but is intended to afford an idea of the scope of the Sullivan Company as manufacturers of air compressors. The booklet describes briefly all the Sullivan lines, including "Straight Line," "Duplex" and "Corliss" steam and belt driven compressors.

## SPECIAL CORRESPONDENCE

### NOVA SCOTIA.

**Glance Bay.—The "Free Coal League" and the Dominion Coal Company.**—The "Free Coal League," which, being interpreted, is said to be Mr. W. C. Milner, no more, no less, is very prominent just now, and, assisted by "Farmer," a gentleman whose literary style is strikingly reminiscent of the secretarial pronouncements of the "League," must relieve very largely the labours of the editorial staff of the Halifax Herald in its search for salty "copy." We have heard it said that Mr. W. C. Milner is—

"The cook and the captain bold and the mate of the 'Free Coal League,'

The bo'sun tight, and the midshipmite, and the crew of the captain's gig."

It would interest the public to see the yearly balance sheet of this society. Judging from the name of the "League," it might be supposed that it was formed to fight for free coal, but from the actions of the secretary the public may be pardoned if they assume that the "League" was formed to fight the Dominion Coal Company. Mr. Milner tilts everlastingly at the Dominion Coal Company, and nothing is too hard for him to say about this "bloated monopoly," this "grasping corporation." When the ordinary man has finished one of Mr. Milner's diatribes against this company he is left wondering at the iniquity of the coal barons, who must appear to him, if he believes all Mr. Milner says, as a compound of Standard Oil, Abdul Hamid and Auld Cloutie himself.

For example, Mr. J. S. Willison contributed an article to the Times, which was admitted by every informed person who read it to be a dispassionate and fair presentation of the Canadian coal mining industry in relation to the question of reciprocity in coal between Canada and the United States. Mr. Milner immediately informs the Herald that the article is "replete with misstatements of fact," as is Mr. Milner's polite manner. Mr. Willison presented in rather a novel table the per-ton profits of the Dominion Coal Company for several years past, and showed the steady decline in these from 1902 to 1908. Mr. Milner contradicts the figures given for 1907, which, he states, are a trifle of \$1,200,000 dollars understated, but Mr. Milner omits to say, what he very well knew, that this represented the extra price paid by the Steel Company during the progress of the litigation which is now ended, and that Mr. Willison's figures were quite correct.

Mr. Milner's chief contention appears to be that the Dominion Coal Company charges less for coal in Montreal than it does in Nova Scotia, and that because it now sends coal to Boston with the duty on, it could send infinitely more to Boston if the duty were taken off. Mr. Milner always carefully forgets to say that the coal now being sent to Boston by the Dominion Coal Company is slack coal, and the Dominion Coal Company only seek this contract as an outlet for their winter slack. The business is not a paying one, and everybody knows that any comparisons or figures based on this slack contract are utterly misleading when applied to the coal export trade as a whole. The Dominion Coal Company can mine coal more cheaply than anyone else in Nova Scotia, and they cannot look at New England business to-day, nor could they with the duty off. Mr. Drummond, of the Mining Record, is the bete noir of the secretary of the "Free Coal League," and we suppose if the last-named gentleman ever has nightmare, the Hon. Robert is the bogey. However, it must be admitted that Mr. Drummond knows what he is talking about when he is on the subject of coal mining in Nova Scotia. In the last number of the Record Mr. Drummond writes:—

"Take off the American and Canadian duties on coal, and then Nova Scotia will have in the New England States a market, so we are told, for millions upon millions of tons. How credulous some people are, or how deceitful. At the present time West Virginian coal is selling f.o.b. Boston at \$2.30 a ton, and in cars at \$3.00. How much money would there be in the New England trade for the Nova Scotia operators at that price? They could not look at it. West Virginia coal, for the time being at any rate, has forced Pennsylvania and Ohio coal out of the Boston market. If West Virginia can drive two neighbouring States to the wall so far as coal shipments are concerned, is it likely she would stand by and allow Nova Scotia to enter and hold the field? It is not to be imagined."

Suppose, for the sake of argument, that it were possible by the provision of costly and adequate discharging facilities for the Dominion Coal Company, or any other Nova Scotian company, to oust or successfully compete with United States coal in the New England States under a reciprocity arrangement (which is supposing an impossibility), what guarantee could a Nova Scotian company have of fair treatment in a foreign country if that country began to feel the pinch of Nova Scotian competition? Would any sane board of directors be justified in expending the huge sums of money that it would be

necessary to expend to get any portion of the New England market, under such circumstances, and what assurance could a Canadian company be given that the duty would not be reimposed? Surely the citizens of Canada have lived alongside of Uncle Sam long enough to know him better than that.

In Mr. Milner's contention that the Dominion Coal Company is doing injustice to Nova Scotian operators by the price of coal it is charging in the Maritime Provinces as compared with its St. Lawrence markets, he entirely ignores the fact that the Dominion Coal Company is supplying practically one-third of its entire output to the Dominion Iron and Steel Company at a figure which is below the cost of mining. Take away from Cape Breton the Dominion Coal Company and the steel industry, which the first-named company in a large measure supports, and what would be the consequences? Mr. Milner attempts to prove that the Dominion Coal Company is an incubus and a hindrance to the legitimate expansion of Nova Scotian industries and the province generally. The fact of the matter is that the incorporation of the Dominion Coal Company was the inception of the greatest impetus that has ever been given to the advancement of the Maritime Provinces. That is a fact that can neither be controverted nor denied.

Mr. Milner's other argument is that coal is sold to the railways and large business concerns in Montreal at a cheaper rate than it is sold to the householder and the Gas Company in Halifax. We very much doubt Mr. Milner's sincerity when he complains of the low price that is paid by the railway companies for their coal, but if he is willing to purchase coal in the same quantities in which it is purchased by the railway companies he could get it at the same price. This condition of affairs is not confined to Nova Scotia. In England coal is sold at the pit mouth to the railway companies at from \$1.50 to \$2 per ton. The same coal is sold to the workmen who mine it at from \$2 to \$2.50, and to outsiders under the screens at from \$3 to \$3.50 per ton. In London, about half the distance from the mines that Halifax is from Cape Breton, the same coal will retail at from \$5 to \$7 per ton. In Germany the same is true, and in the United States it is said the railways take the coal companies by the throat and squeeze them dry. Mr. Milner should take an elementary course in the laws of trade, and he might enquire how it is that Canadian cheese and Nova Scotian apples can be bought for less in London, England, than they can be bought for in Sydney, Nova Scotia, and why the American coal operators can "dump" coal in Canada at prices that may bring them 5 cents profit and may not.

It is a fond hope that the abolition of the duty on American coal would give Ontario and Quebec much cheaper coal. So far as Ontario is concerned, the price of coal would not be reduced one cent. For all practical purposes Ontario is outside the present available territory of the Nova Scotian coal companies. The only hope for Ontario to get cheaper coal is the construction of the Georgian Bay Canal. If this canal is excavated to a depth that will allow the transportation of ocean borne coal from the Maritime Provinces, it would immediately put the Nova Scotian operators in a position to compete with the United States operators in a territory from which at the present time Nova Scotia is barred. The price of coal would then be lowered by reason of Nova Scotia competition. Should this canal be constructed there is no reason why the Nova Scotia coal trade should not extend its territory until it meets the field of the Alberta mines, and Canada would thus be independent of the United States, so far as coal is concerned, throughout the length and breadth of the whole Dominion. So far as Quebec is concerned, a removal of the duty would for a time give the people of that province cheaper coal, but it would only be a temporary reduction. Under such circumstances there would only be three coal companies in the whole of Nova Scotia that would continue to exist, and their output even would decline until American mines would have absolutely no competition in

the Province of Quebec. Then what guarantee have the people of Quebec that the price of coal would remain at reduced figures? It might be raised—it would be raised. Such things have happened, and there are such things as "combines" in the United States. We are told that once upon a time American anthracite coal was sold at \$3 per ton in Ontario, and that to-day it sells at from \$6 to \$7. The same thing would happen to the price of bituminous coal eventually should reciprocity ever be introduced.

We submit that the Dominion Coal Company, Mr. Milner to the contrary notwithstanding, is not a grinding monopoly, but is a beneficent business enterprise which has very greatly increased the prosperity of the Dominion as a whole, and of Nova Scotia in particular. It has not extorted unfair prices for its product, and it has not used the "big stick" on the smaller operators. As an employer of labor its record is good, and in this particular it can challenge the majority of the coal mining companies in this continent. Since the date of its incorporation the company has never had a strike, or a serious labor trouble, and that is sixteen years ago. The present little disturbance has been engineered by a foreign organization, hailing from the country that is now asking free admission of its coal. The conditions of mining cannot be excelled on this continent, and when it is considered that the Dominion Coal Company have produced over 35,000,000 tons in sixteen years, and in that time, with the exception of one small explosion which caused the death of eleven men, they have had no serious disaster causing loss of life, it must be admitted that they are careful miners. This is partly due to naturally safe conditions, but not entirely so. We have advocated this point of view ad nauseam, but it seems necessary. The company is well managed, and conservatively financed, and when Dr. Milner says its stock is watered he does not write the truth. As a matter of fact the capital of the Coal Company is small compared with its vast holdings and possibilities. It possesses what is probably one of the most valuable bituminous coal deposits in the world, and has a plant which always astonishes visiting engineers by reason of its completeness and extent. If anyone doubts the excellent shape of the Dominion Coal Company's properties let him read the published accounts of the recent visit of the British Institution of Mining Engineers, and he will be enlightened from an English point of view. Many of the Coal Company's men have at times gone to the United States to better their fortunes, but they invariably come back, and in many instances have written begging for free transportation, as conditions in the States were not so rosy as painted. The same is true of men from the "Old Country." They go home, but always come back. Safety lamps are a thing of course, high explosives equally so, there is no "shooting" by unskilled men, no "shooting off the solid," and every precaution that is reasonable is taken to preserve life and property. The company's Rescue Station was the first this side of the water. All these matters are carefully ignored by the "Free Coal League."

If the "League" will change its name and call itself "An Association for the Villification of the Dominion Coal Company," it will appear in its true colors. Its present cognomen is not justified, unless by "free coal" we are to understand Mr. Milner would like to get his fuel for nothing at all!

#### **The Aftermath of the Conciliation Board.**

Some few days after the publication of the findings of the Board of Conciliation which recently sat at Glace Bay, two emissaries of the U.M.W.A. arrived in town with cheques to the amount of \$20,000, which they deposited in one of the banks. All the available newspaper reporters were asked in to the bank to assist in the ceremony, and their attention was carefully called to the fact that the cheques represented real money, and, further, there was lots more where that came from. This

theatrical proceeding was followed by various high-flown utterances, which duly appeared in all the glory of print, for the edification of all true believers. The consideration given by the local press to the utterances of the U.M.W.A. delegates has been carried to the point of indulgence, and whatever else these uninvited and unwelcome disturbers of the public weal may have done—and they have very much to answer for—they have plainly impressed the local newspapers. One Sydney newspaper thus described the journeyings of one of these walking delegates: "By the Intercolonial Express this morning Mr. H. W. Bousfield, plenipotentiary extraordinary of the United Mine Workers of America, who has for some days been visiting the Cape Breton coal region," etc. This was written in all seriousness, and was followed by three and a half columns of the things that the American ambassador had deigned to import to the listening reporter. It is no wonder that some of our visitors become afflicted with a further accession of vanity when they see how seriously supposedly reputable newspapers take their vaporings, and some of them really begin to think they are making a noise in the world. This particular agitation was begun and has been fostered right up to the present time by newspaper talk, and garbled, and even actually untrue statements have appeared in Montreal newspapers, that should have known better than to print unedited news from unreliable correspondents. Until we get two days' old newspapers from Montreal we never realize down here how interesting events have been in Cape Breton. A large proportion of the "news" about Cape Breton that has appeared of late in the Montreal and Toronto newspapers is really fiction, and such fiction as speaks volumes for the imagination of correspondents and the credulity of editors.

The latest addition to the forces that are seeking to disrupt the public peace in the mining districts is a rag that is outside the pale of decent newspaperdom. This broadsheet is called "Cotton's Weekly," and is printed at Cowansville, P.Q. Some persons unknown have kindly distributed broadcast a large number of copies of this paper, and a few excerpts may show the kind of literature to which we are being treated. Referring to the Glace Bay Board of Conciliation this sheet remarks editorially that the two arbitrators were "either knaves or fools." "These huckstering arbitrators, although they can get their opinions splurged through the columns of the capitalist press, will not befoozle the workers." This is rather a severe castigation of two gentlemen who voluntarily performed an irksome and thankless duty to the best of their ability. We would like to know exactly what operation is covered by the verb "to splurge." It is cheering to note that the total circulation of this poisonous rag is only 2,400 altogether, and Prince Edward Island takes but two copies. P. E. Island should be thankful. "Cotton's Weekly" bestows its blessing upon the U.M.W.A., and refers to the P.W.A. as "the pet of the big companies." It is interesting to know the company that is kept by the U.M.W.A., and it would be more interesting to know who paid for the free distribution of these papers.

"Cotton's Weekly," like its friend the U.M.W.A., has a decided dislike for the Lemieux Act, which it terms a "capitalistic law for squeezing the workers." Evidently the Canadian socialist does not know advanced social legislation when he meets it. The principles and the workings of the Lemieux Act have evoked warm encomiums from socialist newspapers and reviews in other countries. Just recently "Der Sozialpraxis," a prominent review dealing with social politics, published in Berlin, has devoted a good deal of space to the consideration of the Lemieux Act, and sums up its conclusions as follows: "The Canadian Parliament has evidently achieved something great in passing the Lemieux Act, which provides a Court of Arbitration, and so far its advantages have greatly preponderated over its failures. The happy solution Canada has found to the difficulties which are so often arising with

regard to coal mines, railways, etc., might well serve as a model for the legislators of many European countries." The German review pays a graceful compliment to the soundness of the legislation which has distinguished the over-seas Dominions of the British Empire. In Canada most people are content to judge by results, and there have been few pieces of legislation which have had such ample justification in so short a time as the Industrial Disputes Act of Canada. It is but natural that the U.M.W.A. should dislike the Lemieux Act. The U.M.W.A. has its headquarters in a country that is several laps behind Canada in the matter of social legislation, a country where industrial disputes are largely settled by such crude methods as strikes and lock-outs. We are a long way beyond that stage of development here, and in Canadian eyes the U.M.W.A. is a body of reactionaries, a reversion to the primal type. Industrial conditions in Canada are far better than they are in the United States, and so far as relates to the condition of the mining population life is much pleasanter for the miner in Cape Breton than it is in Pittsburg. Some interesting independent testimony was given on this in the House of Commons by Mr. Ralph Smith, the member for Nanaimo. Mr. Smith stated that he had spent some time in investigating the conditions under which the mining population of the Pittsburg district were living, and his remarks may be quoted with profit. Mr. Smith says: "After a man has gone through an experience of this kind he is prepared to regard even the worst conditions in Canada as favorable in comparison. I want to say that the coal miners of England fifty years ago were in a better condition than the coal miners in the surroundings of Pittsburg are to-day. . . . In hours of labor, in wages, in the prices of commodities that they require to use, our industrial classes in Canada are very much better off than those in that old settled district of Pittsburg. . . . Therefore I say that we have reason to congratulate ourselves that we are so favorably situated." To put it plainly, the Canadian miner, did he but know it, is in a position to act as teacher to his comrades in the United States, and he is doing despite to his privileges when he consents to follow the guidance of the U.M.W. of America.

#### QUEBEC.

**Thetford Mines.**—Work at the various mines is progressing on about the same scale as last season. It is expected, however, that the production will be materially increased as the season advances. The new properties are pushing their building and development as rapidly as possible. The Thetford Asbestos and Exploration Co. have three cable derricks under way, and are removing the earth-burden so as to be ready for mining operations as soon as the mill is finished. The plans for the mill are about ready and building will be pushed rapidly. The mineral showing is good. The Robertson Asbestos Co. have their mill nearly ready and hope to be producing early in June. The Imperial Asbestos Co., at Black Lake, have their plans under way for their mill. C. S. Saunders is appointed manager for the new company.

The Royal Trust Company, of Montreal, is reported to have bought one-third interest in the Ward-Ross property, s.w. half Lot 27, Range V., Thetford. The price named is \$100,000.

Recent visitors to the town are Earle C. Bacon, New York; Messrs. J. A. Jacobs and Mortimer Davis, Montreal; N. A. Timmins, Haileybury, Ont., and Messrs. Sam and Charles Turner, of Turner Bros., Rochdale, England. The McGill mining students, in charge of Mr. John A. Dresser, made an inspection of the camp on April 28th and 29th.

**Black Lake.**—The Union Asbestos Mines, Alfred Calmon, Hamburg, Germany, is under option till May 30th to McCuaig & Co., Montreal.

**East Broughton.**—The Boston Asbestos Co., the Broughton Asbestos Co., and the Ling Asbestos Co. are the present producers, with the Frontenac and Eastern Townships Asbestos Companies to commence at an early date. The Broughton Asbestos Company have just changed from steam motive power to electricity, which is supplied by the Shawinigan power lines. Mr. J. J. Penhole is appointed manager for the Ling Asbestos Company.

**Danville.**—The Asbestos and Asbestic Company are working their mill two shifts as usual. The new mill, which is about completed, is of particular interest on account of several new features introduced into the Cyclone whereby the deteriorating influences, which in the past have been the serious objection to this machine, will be reduced to a minimum.

**Capelton.**—The mines of the Nichols' Chemical Company have been closed for a considerable period. The old ore bodies were worked out as completely as possible. The company's chemical works are producing as usual from ore received from the surrounding locality, and particularly from the Eustis Mining Company. The Eustis Mining Company, under Superintendent Adsit, is working vigorously and producing about four thousand tons per month. A modification of the milling system similar to that used by the Granby Mines, B.C., is being employed and with good success. The motive power is supplied by an up-to-date electric plant.

Considerable speculative conversation is indulged in bearing upon the importance of the copper deposits of the Eastern Townships, and indications point to a movement in prospecting for this mineral and developing old, abandoned workings as soon as the price of the metal reaches the proper figure. J. R. Duckett, of Montreal, has taken option on several hundred acres of land near St. Joseph, Beauce, from which he shows very fine samples of bornite and chalcocite in a vein two feet wide. He purposes to proceed with development at once. Apropos abandoned workings and prospects, we are much interested in R. W. Brock's suggestion in April 15th Journal regarding an "Inventory of Promising Mineral Claims." We think Quebec heads the provinces for the number of mineral claims just opened up and now lying dormant, and also for lack of knowledge regarding these, and even of properties of proved importance. Mr. Brock's scheme would prove a great saving of time and capital and unquestionably an impetus to the mineral industry.

#### ONTARIO.

**Cobalt.**—Under date of May 1st it was stated that Mr. J. Houston, of the Right of Way Mine, had been appointed consulting engineer for the Nipissing. This was a mistake as Mr. Houston has been appointed consulting engineer for the Little Nipissing, not the Nipissing.

In our issue of March 15 the statement was made that Mr. Bannell-Sawyer had bought the Milne property. This has not been confirmed.

Three new boilers are being installed at the O'Brien Mine. Two are 150 h.p. each and one is 100 h.p., the working pressure for all three being 150 pounds. These boilers are manufactured by Goldie McCulloch and are to be used to supply power to run the big 250 k.w. generator, which will be direct connected to the engine.

The Kerr Lake will probably make an addition to their plant in the shape of a new 12-drill compressor. The main shaft on the No. 3 vein will be continued to greater depth. The vein in the lowest level shows a good width of very rich ore.

A party of business men from the Maritime Provinces recently came to Cobalt to look over some of the principal

mines and to obtain an unbiased opinion of the possibilities of the district. Although their stay was only a short one they saw enough to fully convince them of the greatness of the mines.

Captain Jeffreys has sent in his resignation as superintendent of the Chambers Ferland. Mr. Chas. Watson, of the Nipissing, is temporarily filling the position.

To those best posted on conditions in this district it would appear that before long the majority of the mines in Cobalt will be controlled by two or three syndicates. The Consolidation of the La Rose properties was one of the first indications of the change, and the recent change in the management of the Chambers Ferland would seem to indicate that this property will be absorbed by the Nipissing. The Lewishons have control of the Kerr Lake, and have also at the present time a deal on for the purchase of the Drummond. It is well known in camp that they are anxious to increase their holdings and that they have bid high for one or two other important mines. The Jacobs Exploration Company is also another important factor, owning many properties in Coleman and Lorraine. It is stated that the Nevins interest in the Cobalt Central have acquired control of the Foster.

A rich strike was made at Temiskaming Mine on April 30th on their No. 4 vein. The ore was encountered in a winze, sunk from a cross-cut, midway between the two shafts on the 250 foot level, and will run about 30 inches in width, of high grade ore. The find was made at a depth of 280 feet from the surface, which is so far the deepest working on the property, and will have a very important bearing on the future of the mine. Despite the many unfavorable rumors concerning the Temiskaming, the mine was never in better shape and the development work is kept well ahead of the stoping. The ore in the 250 foot level is even higher grade than that encountered in the upper workings and the work of sinking the main shaft is being steadily pushed forward so that new levels may be opened up.

The annual report of the Nipissing Mines lately issued shows that in 1908 the company shipped 2,803 tons of low grade and 702 tons of high grade, having a total silver content of 2,893,931 ounces, with a net value of \$1,363,783. The total cost of production was \$575,213, or a little over 20 cents per ounce. The cost of production may seem high in comparison with some of the other mines, but the large number of workings, located at considerable distance from one another, will account for a large administration and mining expense. The company has the largest acreage of any in camp, 846 acres, a large portion of which is still practically unprospected. The large ore body found some time ago in the No. 64 shaft is being developed, a drift having been run nearly sixty feet on the vein, which shows for the entire length an average of 16 inches of high grade ore. The ore reserves of the Nipissing are at present estimated to be about \$2,500,000.

After lying undeveloped for about five years work is at last to be started on the famous Lawson property. This property has been taken over by the La Rose and paid for by the issue of treasury stock which was kept for that purpose. For the present the base of operations will be in the old shaft at the northern end of the property, which was sunk by the Silver Leaf Co. Through an error in the survey this shaft was sunk and the Lawson lot instead of the Silver Leaf. Drifts will be run to the south on the vein, and it will probably not be long before shipments will be made.

On April 22nd a new vein was discovered on the surface, at the Chambers Ferland. The vein lies behind the company's office, about 250 feet distant from the No. 2 shaft, and is from two to three inches in width, carrying smaltite and some silver values. The east cross-cut from the 80-foot level of the No. 2 shaft will need to be continued only about forty

feet to tap the vein. Drifting is being carried on from the bottom of the No. 1 shaft and raise will be started from the drift to connect with the upper body preparatory to stoping. Work has been started on the La Rose vein, which was caught last fall by the Right of Way, while working for the Chambers Ferland, and the vein is holding its original width and values. Twenty-five additional men have started work surface prospecting, and this force will be largely augmented during the next few weeks. The management expect to discover several of the Nipissing and La Rose veins in the north and west ends of the property. The Chambers Ferland is one of the heaviest shippers in the camp and it is well within the range of possibilities that it should become a dividend payer in the near future.

It is reported that two new high grade veins have been discovered by the diamond drill working on the Drummond.

A plant will shortly be installed at the Bailey Mine which will probably consist of two 100 h.p. boilers and a 12-drill compressor. Meanwhile the development work is being pushed as rapidly as the limited facilities will allow.

The Silver Lode Mining Co. at Cross Lake, formerly known as the Queen Alexandria, will install a plant consisting of a 30 h.p. boiler, a hoist, and two drills. The shaft has already been sunk to a depth of 75 feet and will be continued deeper.

It is stated that the Haileybury Silver Mining Co. have sold the south half of their property, consisting of twenty acres, to New York and Buffalo parties for \$100,000. The money realized from the sale will probably be used in developing on a more extensive scale the remaining twenty acres.

A force of men are now engaged in surface prospecting at the Kerr Lake Majestic. The underground development is also making good progress, and the main shaft is now down over 75 feet. Sinking will be continued to the 125 foot level before a station is cut.

A surface vein showing good silver values has recently been discovered on the Farah property.

Good progress is being made at the Empire Mine, which now has a force of about 16 men at work. The shaft has been sunk nearly 100 feet, and will be continued to greater depth.

A contract has been let to sink a shaft on the property of the Cobalt Bullion Mining Co., near Sasaginaga Lake. It is probable that some diamond drilling will also be done.

Another strike has been made on the Right of Way while cross-cutting from their No. 3 shaft. The ore is high grade and was discovered on the 75 foot level about 350 feet from the shaft.

A new vein has been discovered on the property of the John Black Mining Co. The vein matter consists of calcite, with some smallite and low silver values, and was discovered 200 feet north from the main shaft. The shaft is now down forty feet, and when the 100 foot level is reached a cross-cut will be run to tap the vein. The steam plant recently installed is supplying power for one drill.

The Little Nipissing expects to start work shortly sinking the shaft on their property at Short Lake. The shaft is now down 60 feet and will be continued to the 150 foot level. Air will be obtained from the Silver Queen Mine.

It is reported that the Silver Bird has been leased to the Michigan Development Co. and that work on the property will be started shortly. The mine is located north of the Colonial, on Farr Creek.

The Silver Cliff Mine, which has been closed down for some time, will again commence operations under the management of the original owners.

At the Otisse Mine a four-inch calcite vein with high values in native silver has been encountered in the cross-cut at the 70 foot level.

The Johnston Mines, Limited, owning seventeen claims in Coleman, have let a contract for sinking a 125 foot shaft on one of their properties.

The Motherlode Mine, in James Township, purpose sinking a 100 foot shaft near the mouth of the tunnel, and it is expected that the vein will be cut at that depth. So far all the work has been carried on from the tunnel, which is now in over 300 feet, and the vein continues to show good silver values. A winze has been sunk 50 feet below the level of the tunnel, and from the bottom a 60-foot drift was run on the vein which shows the same width and values as above.

Great activity is being displayed in the Elk Lake district, which promises to become one of the important mining sections. A steam plant is being installed on the Cummings properties and two of the boilers are already on the ground. A shaft will be sunk to the 100 foot level. The United States Mine have let a contract to sink two shafts, 100 feet each, with 200 feet of drifting at the bottom. The Silver Alliance Mine, adjoining the United States on the west, are sinking two shafts by contract, each of which is down about 45 feet. Good progress is being made at the Elk Lake Cobalt Mines and a large force of men are engaged in the mining operations and the installation of the plant, which will shortly be running. The shaft is down to the 100 foot level and will probably be continued much deeper. Several other smaller properties in this district are preparing to operate during the summer months.

The "Big 6" Mine is installing a plant consisting of two 40 h.p. boilers, a four drill Rand compressor, dynamo, pumps, etc. As some of the machinery arrived too late to be taken in over the winter roads the plant will not be in operation until after the opening of navigation, when the remainder can be taken in. The main shaft is now down over 75 feet and will be continued deeper before stations are cut. A force of 26 men are at present employed on the property.

The plant of the Montrose Syndicate, in Lorraine, is now running and the development work is proceeding much faster in consequence. A new head frame has been erected and also a new boiler-house near the shaft. The shaft is down 40 feet and will be sunk 100 feet before any drifting is done.

Air for the Pan Silver is being obtained from the Temiskaming. The shaft is now down about 150 feet, and 25 men are employed on the property.

A contract has been let by the Gifford Cobalt to sink their shaft an additional 90 feet from the 110 foot level.

Mr. J. Houston has resigned his position as superintendent of the Right of Way and will go up the river to take charge of the Bonsall claims. It is probable that he will be retained by the Right of Way as their consulting engineer.

Shipments for the month of April were 2,493 tons, and for the first four months of the year 9,459 tons. This is considerably in excess of the corresponding periods for last year.

The number of deaths lately, due to accidents in the mines of the Cobalt district, points more than ever to the need of an inspector to be located permanently in this district. The present inspection is excellent as far as it goes, but the field that the inspector has to cover is so large that visits to the mines here can only be made at long intervals and as a consequence many of his recommendations are partially, if not wholly, ignored. When an inspector has made his visit to the mine and notified the management of the changes necessary, he should have the time at his disposal to revisit the mine in the course of a week or two, to see that these changes have been made. Under present conditions this is absolutely impossible. It is undoubtedly true that in some of the mines the management is lax in looking after the safety of their men as it should be done, and there is plenty of work in this camp alone to keep an inspector busy all the time.

## BRITISH COLUMBIA.

**Rossland.**—Indications point to a profitable year for the mines of this district, even though there have been a number of drawbacks so far this season. All over the province there is a healthy activity, and while some of the big mining companies are playing for time until copper strengthens a little, yet they are, or will be, in a splendid position to take advantage of a rise in price when it comes about, which we anticipate may be in the months of July or August. Here at Rossland the Centre Star-War Eagle group of the Consolidated Co. is right now in a position to more than double its output; the Le Roi 2, Limited, could also increase its output, although its main efforts will be concentrated on the retimbering and deepening of the Josie shaft from the 900 to the 1,200 ft. levels for a while to come. It is hoped that an extensive plan of operations will be laid out for the Le Roi and with the prices of copper and silver at an advance over present quotations there is a quantity of ore in the mine that could be shipped at a fair profit.

At the present writing there are about 570 men working at the Centre Star group, Le Roi 2, Limited, Blue Bird, I. X. L., Hattie Brown, and O. K. mines, the pay roll running about \$60,000 per month, but this force will be materially increased before the season has gone much farther.

The Le Roi 2, Limited, is making a very good showing. A diamond drill hole put down on the 400-ft. level to locate the continuation of the ore in the 301 stope met with ore from 299 to 308 ft., 5½ ft. of which assayed 1 oz. 10 dwt. gold and 1.81 per cent. copper. During the month of March the Le Roi 2, Limited, shipped to Trail smelter 2,620 tons of ore. The total smelter receipts were \$62,361, in settlement of 112 tons of concentrates at \$29.55, and 3,263 tons of ore at \$18.11, net over and above freight and treatment charges. This is a fine average for Rossland ore.

The Centre Star group of the Consolidated Co. continues to make over \$30,000 per month net on each month's operations. The average grade of ore extracted during March was \$11.10 per ton. The ore body on the ninth level of the War Eagle opened up 50 feet wide, carrying \$20 to \$50 gold per ton. During March the Centre Star-War Eagle group shipped approximately 14,000 tons of ore, which if it averaged \$11.10 per ton, and the freight and treatment charges are under \$5.55 would leave a gross profit on the operations of the mine for the month of over \$77,000. The last month at the Consolidated Co. Trail smelter was the largest in the history of that plant in the way of silver bullion production. A record was also made in the refinery turning out pig lead. Including the work at the St. Eugene, which is showing up a lot of new ore, it is estimated the Consolidated profits last month were about \$70,000 net. It is not thought that the Southern Alberta coal strike will affect any of the properties of the Consolidated as this concern has several months' fuel in the bins.

The ledge on the Hattie Brown has opened out to 6 feet in width and a strike of ruby silver is reported in the shaft. The lessees of both the O. K. and I. X. L. have ore sacked and ready for shipment. The prospects for activity in the leasing way in this camp during the coming summer are good as a number of the old miners who have their homes here have determined to keep themselves busy and try and make a strike in this way during the next few months.

**The Boundary.**—Ore shipments in the Boundary have dropped off a little in the last couple of weeks, the Oro Denoro not shipping and the Granby only mining enough to keep part of its furnace battery at the smelter glowing, two of the furnaces now undergoing the enlarging process. By July this augmentation of the entire eight furnaces will have been completed and the Granby will have a smelting capacity of 4,500 tons per day and the mines and smelter will be worked to full

capacity if the price of copper warrants such action at that time. This would mean 135,000 tons per month, or 1,620,000 tons per year, if steady operation could be maintained, but this is a physical impossibility as drawbacks in the way of labor, fuel and repairs are almost bound to crop up. It is anticipated, however, that the tonnage for this year will exceed that of last, when it was 1,037,544 tons, returning net profits of something over \$700,000. A mine like the Granby property, however, does more for the good of the community and classes than, we will say, some of the mines at Cobalt. Where the Granby has to employ extensive means and men and a big plant to take out and treat its million tons of ore and make a profit of \$700,000 it is said 2,000 tons of Cobalt ore will yield the same profit, most of which the classes never get a glimpse of—except the capitalist class.

The British Columbia Copper Co. has put a small force of men at work in the Oro Denoro mine. It is likely, however, that all of the property of the B. C. Copper Co. will be closed down unless the company makes arrangements for a coke supply other than that from Coleman, where there is now a strike in progress. A conciliation board, under the Lemieux Act, has been appointed, to settle some minor differences between the B. C. Copper Co. and the Miners' Union. A shut-down would give the contending parties a lot of spare time to talk things over.

A large body of good ore has been opened up in the Greyhound, which adjoins the Mother Lode. This is a promising property and will be heard from later in the annals of Boundary mining history.

Frederic Keffer, consulting engineer for the British Columbia Copper Co., has been over the coal fields of Nicola and Princeton districts. There is a probability of these coal fields supplying fuel for the Boundary mines and smelters in the not distant future. A considerable saving in freight could no doubt be effected over fuel brought in from the Crow's Nest and other outlying points.

The Nicola Valley Mines are now shipping more than at any time heretofore. During February and March 16,000 tons were produced, but it is estimated that April shipments will exceed both of these two months combined. A new steel tippie and other facilities will be installed soon, when shipments can be materially increased.

The Protective Committee in Dominion Copper affairs has appointed Price, Waterhouse & Co., chartered accountants, to audit the accounts of the company; it also states that a mining engineer of high standing in the profession is to examine the property. This committee claims to have 300,000 shares of stock and \$100,000 in bonds behind its actions. We can only trust that the thing will be equitably adjusted in the end, but the whole thing looks pretty hazy just now.

**Nelson District.**—The Canadian Metal Co. is going into voluntary liquidation at a meeting to be held in Nelson on June 12th. S. S. Fowler, engineer, Nelson, will be appointed liquidator. A new company is to be formed, known as the New Canadian Metal Co., with a capital of \$1,100,000; 100,000 shares par value \$10, and 100,000 dividend shares par value \$1 each. The shares in the new company will be issued 75 per cent. fully paid, leaving 25 per cent. to be paid by the subscribers for stock in the new company. This is where the old shareholders "dig up" or "drop out." The Canadian Metal Co. did not have much luck in its operations and has dismantled its zinc smelter erected at Frank, Alberta. The company is still interested in mines and at Pilot Bay smelter, these to be turned over to the new concern.

The new coal handling plant of the Crow's Nest Pass Coal Co. at Fernie, B.C., is now working. It is said to be one of

the largest in Canada, handling 12 tons per minute with 17 men. This work formerly required 68 men.

A good strike of magnetic iron ore is reported as having been made on Campbell River, Vancouver Island. J. McLennan, D. McPhee and S. Smith have each staked claims along the showing, which averages 20 feet in width. The property is easily accessible for development and there is coal and timber close at hand.

## GENERAL MINING NEWS.

### NOVA SCOTIA.

**Sydney.**—The Dominion Steel Company has received an order from the Great Northern Railway Company, of Sheffield, Eng., for 5,000 tons of steel rails. The rails are of standard lengths and 85 pounds weight. This is the first order the company has received from an English firm. New rolls have had to be made to fill this order, as specifications for contract call for bullhead rails, widely different from the ordinary flange in use in Canada.

A Sydney paper says: "At this date the Nova Scotia Steel and Coal Company have at least 120,000 tons of coal banked at its several collieries, and this quantity is ample to supply its steel plant for fully eighteen months, so that in the event of the miners being called out at these collieries the steel plant can still be operated to its full capacity for a year and a half."

The U. M. W. A. have applied for another conciliation board to adjust some grievances between the United Mine Workers employed by the Nova Scotia Steel and Coal Company and that company. An increase in the wages of miners compelled to work with safety lamps is demanded, as it is claimed that the lamps lessen the earning power. The men also claim that the employees at No. 3 Colliery are discriminated against because they are members of the U. M. W. A.

A syndicate has been formed to go into the coal carrying trade. One steamer has already been purchased, and the acquisition of a number of others this year is being considered. The syndicate was formed as a result of the withdrawal from the Canadian coasting trade of all foreign steamers of under fifteen hundred tons.

### QUEBEC.

**Thetford.**—The Beaver Asbestos Mines have suspended operations for a time. The 250 men employed refused to work because an additional half hour's work every day was asked of them in order to pay for the laborers' insurance. This strike will not cause big damage, as the demand for the mine's products is not great at present.

### ONTARIO.

**Cobalt.**—The La Rose has taken over the famous Lawson mine, which has been involved in bitter litigation practically since its discovery in 1905. The La Rose Company will start immediately to develop and prospect the Lawson, which is one of the richest properties in the Cobalt district.

Eight drills are at work on the Crown Reserve. Six machine drills are being used for development work and two stopping drills in taking down ore on the main vein.

The Kerr Lake is now mining the deepest in the camp, and have six inches of ore at a depth of 400 feet. There are seventeen veins on the property which show pay ore.

Of the 846 acres owned by the Kerr Lake Company, 383 are still unexplored, and the remaining 463 acres are only partially prospected and developed. The recent discovery of a well-defined vein of rich ore at the 172-foot level in shaft No. 64,

which is 16 inches in width and assays 1,700 ounces of silver to the ton, shows the possibilities of this partially prospected territory.

A shaft is down 140 feet on No. 3 vein of the Savage mine, with levels cut at the 75 and 135 foot levels. On the 75-foot level 100 feet of drifting has been done, and cross-cutting to the vein on the 135-foot level has been started.

Six concentrators are now in operation at Cobalt, and four more are in course of erection. During 1908 ten smelters treated ore from the camp. The shipments during 1908 were greater than the combined shipments of the four previous years. There are now 3,500 men employed in the mines in this district.

The Little Nipissing expect to start sinking the shaft on their Short Lake property shortly. Air connections have been made with the Silver Queen, and a drill will be installed. The shaft is down 60 feet on an 18-inch calcite vein, and the shaft is to be continued to the 150-foot level before a station is cut.

**Gowganda.**—C. H. Fullerton, civil engineer, has been sent north by the Department of Public Works to survey the route for the summer road to Gowganda. The estimated distance is 32 miles. Construction is to begin about June 1st.

**Toronto.**—The Ontario Government has decided to sell a portion of the Gillies timber limit, and tenders will be received until June 15th. One thousand acres in the north end of the limit are to be put on sale in parcels of twenty acres each, and will be sold subject to a ten per cent. royalty on all ore produced. The total area of the limit is 100 square miles, or 64,000 acres. The portion of the area containing the Provincial Mine is reserved, and will not be put on sale.

1,439,300 acres of land in the District of Algoma have been thrown open to prospectors. The land lies north of Sault Ste. Marie, and is to be open for prospecting until December 31st, 1910. Any iron, coal, iron pyrites or nickel is reserved for the Algoma Central and Hudson Bay Railway, under the terms of the grant made to the company when the land was set aside about five years ago.

### ALBERTA.

**Lethbridge.**—Practically all the coal mines in Alberta are now idle as a result of the strike. A meeting was held at Taber, and the miners made a demand that none but union miners be employed in the mines. This was refused, and as a result the miners stopped work.

The situation continues practically the same throughout the other Alberta camps. Some places are beginning to suffer through shortage of coal.

### BRITISH COLUMBIA.

**Rossland.**—At the present time the Rossland mines employ 565 men, and the pay roll is \$58,000 per month. The Centre Star leads with 410 men on the pay rolls, followed by Le Roi No. 2 with 125 men. In 1905 the average number employed was 750, and in 1908 it was something over 800.

**Greenwood.**—In the dispute over wages and hours between the B. C. Copper Co. and its men, the company has nominated Mr. E. Crown, barrister, of Toronto, as its representative on the Conciliation Board. Mr. John McInnes, M.P.P., represents the employees.

The B. C. Copper Company's Mother Lode Mine has been closed down as a result of the coal strike, and the smelter was expected to close down May 1st, as its reserve coke supply was all exhausted.

**Ymir.**—At the Yankee Girl there are at present 25 men at work. The tunnel is now in 1,500 feet in ore valued at from \$20 to \$60. Arrangements are under way to take up all deferred payments on the property. A tramway and concentrator are planned, but will not be erected at present.

**Nelson.**—At the Queen Mine at Salmo, work is at present being carried on in the 500-foot level. The lowest grade ore so far milled has averaged between \$8 and \$9 per ton. The property produces approximately a \$5,000 brick every 14 days. The mill capacity of 10 stamps has been doubled.

Harry L. Rodgers has taken a bond on the Iona group on Poreupine Creek, owned by Messrs. Price and Burgess.

The bondholders of the Summit group have decided to float a company to operate the property.

**Kaslo.**—At the Lucky Jim changes appear to have taken place in the grade of the ore as development work proceeded. The zinc zone has been worked through and an extensive body of silver-lead ore cut into.

## MINING NEWS OF THE WORLD.

### GREAT BRITAIN.

The Anthracite Miners' Association has demanded an increase of 5 per cent., on the ground of the high prices of anthracite compared with other coals. Should a strike take place, 12,000 men will be involved. The increase is over £60,000 a year.

On December 31st, 1908, there were 515 blast furnaces standing in Great Britain, of which 310 were in blast and 203 idle. This compares with previous quarters of 1908 as follows: March, 12 in blast; June, 308; September, 301. On December 31st there were five new furnaces under construction, and 70 being relined and repaired.

### RUSSIA.

A committee of the Gold and Platinum Miners' Association of Russia has been investigating the possibility of substitutes for platinum, and it reports that there is little likelihood of a substitute being found to take the place of platinum in most of its commercial uses.

Experiments are being made in Russia to produce briquettes, using naphtha as a binding material. Hitherto the difficulty in the way of producing briquettes in Russia has been the need for importing the tar requisite for binding the small coal.

Owing to the depression in the platinum mining industry the platinum miners have applied to the Russian Government, asking that the industry be upheld until it is definitely decided whether the mining of platinum is to be made a monopoly of the Russian Government.

### ROUMANIA.

The Roumanian Minister of Commerce has introduced a bill to authorize the leasing of petroliferous fields in the possession of the state. The fields are to be let in lots of 75 acres. Work to commence within six months from the granting of the concession, and two boreholes must be set up yearly.

### SOUTH AFRICA.

It is rumored that there has been an important reef discovery in the southern part of the Heidelberg district. The spot where the discovery was made is about 60 miles southeast of Johannesburg, and it is stated that investigations prove the

existence of this gold carrier over 12 farms. The reef in question is co-related to the main reef.

In 1907 the total applications of capital to South African mining enterprises was nearly a quarter of a million sterling. In the first three-quarters of 1908 these applications totalled nearly two millions sterling, and in the last quarter of the year they amounted to £865,000.

A discovery of tin is reported from Rhodesia, said to be the site of an ancient tin working. The ancient workers put a shaft down 12 feet, but a shaft recently put down 30 feet showed tin associated with iron and copper in chlorite schist. The formation is the same as the Herberton tin fields in Queensland.

At the present time there are four companies on the Rand which crush 50,000 tons of ore per month, whilst there are a number of plants with slightly less than this. According to the plans of some of the companies, in the near future these figures will be doubled or even trebled.

Over 25,000 tons of chrome ore, valued at about £68,000, having been already exported from Southern Rhodesia, it has been decided to proceed with the construction of a railway line from Selukwe to tap the chrome ore fields. This extension will considerably lessen the cost of transport of ore, and thereby give an increased impetus to mining operations in the Selukwe district.

### AUSTRALASIA.

Further trouble has occurred amongst the miners at Broken Hill. Five hundred men belonging to the Junction North Mine have gone on strike as the result of the dismissal of a unionist miner. Employees at other mines threaten to strike owing to the employment of non-unionists.

The New South Wales Minister for Education has established day schools at the technical colleges at Ultimo and Newcastle. They will provide training in engineering, mining, and architecture.

### UNITED STATES.

The farmers of Deer Lodge Valley, who have been in court actions with the Amalgamated Copper Co. in an effort to close the Washoe smelter at Anaconda, have abandoned the fight, and are now seeking to get a settlement with the company through arbitration or sale of their farms to the Amalgamated.

The Minnesota Senate has passed a bill placing a tax of about 5 cents per ton on iron ore mined in the State.

Copper stocks in the United States are estimated to exceed 182,000,000 pounds, which is 18 per cent. of the total annual production. The addition to this surplus during March amounted to 8,350,000 pounds, or 7.5 per cent. of the total monthly output. It is evident, therefore, that the stocks of marketable copper are not accumulating at an increasing rate.

## Company Notes.

### RIGHT OF WAY BONUS.

A bonus of 10 per cent. has been declared by the Right of Way Mining Co., payable May 20th, to stock of record May 15th.

### COAL AND COKE DIVIDEND.

The International Coal and Coke Co., Coleman, Alta., have declared a dividend of  $11\frac{1}{4}$  per cent. for the quarter, payable May 1st, to stockholders of record April 20.

### EXTRA BUFFALO DIVIDEND.

The Buffalo directors have declared an extra dividend of 3 per cent., payable May 15, to holders of record May 5. The Buffalo pays 5 per cent. a quarter and 1 per cent. extra a month. This 3 per cent. extra just declared is presumably for February, March and April.

### THE PACIFIC PASS COAL FIELDS, LIMITED.

A company has been formed in Montreal under the name of the Pacific Pass Coal Fields, Limited. The company's property consists of 30,000 acres, situated on the headwaters of the McLeod, Embarras and Pembina Rivers, about 40 miles from the main line of the G. T. P., in the Province of Alberta. It is held under a 21 years' lease from the Dominion Government,

renewable for another term of 21 years. The coal is bituminous of good quality. The measures lie almost horizontally, and practically all above water level, thus making the operations self-draining and capable of gravity haulage.

The company has a total outstanding bond issue of \$1,250,000 and an authorized capital of \$5,000,000, of which \$4,000,000 has been issued. The company will at first have a capacity of 750,000 tons of coal annually, for which there is already an assured market.

The Board of Directors is as follows: Mr. E. B. Greenshields, President; Hon. Robert Mackay, Vice-President; Mr. Wm. Molson Macpherson, John Theo. Ross, H. A. Lovett, K.C., R. Brutinel, Edmonton Mineralogist; A. H. Cook, K.C., A. de Bernis, J. W. McConnell and F. L. Wanklyn. Executive Committee—E. B. Greenshields, H. A. Lovett, K.C., J. W. McConnell. Secretary-Treasurer, R. P. Doucet.

### SILVER QUEEN HOLDS ANNUAL MEETING.

The Cobalt Silver Queen Mining Company held their annual meeting April 27th. No dividend was announced, the directors having decided to withhold dividends while the mine workings are in poor ore, as they are at present. The financial statement showed liabilities outside of capital stock (\$1,500,000) of \$14,223. Against this the mine, equipment, offices and assay laboratory are set down at \$1,465,836. Other assets are: Sundry debtors, including smelter certificates, power rental, etc., \$7,751; ore on hand and at smelters, \$13,000; dump (estimated), \$25,000, and cash \$2,633. The ore on hand and in transit and cash balance amounts to \$40,633.

At the end of the last financial year cash on hand amounted to \$54,861.51. With this balance and what the mine has produced the company has paid to shareholders \$195,000 in dividends, besides what has been spent in development work and in installing a new and larger plant. The new 12-drill compressor is producing more air than required, and the excess is sold, realizing \$1,000 a month. The Northern Customs concentrator will begin treating the dump of May 5th.

The Board of Directors is as follows:—Lieut.-Col. John I. Davidson, President; F. L. Culver, First Vice-President; R. W. Gordon, Second Vice-President; J. H. Stephens, General Manager and Secretary-Treasurer; A. J. Young, Director.

## STATISTICS AND RETURNS.

### DOMINION STEEL OUTPUT.

The Dominion Iron and Steel Company's output for eleven months ending April 30 shows as follows:—

|                | 1909.<br>tons. | 1908.<br>tons. |
|----------------|----------------|----------------|
| Pig iron ..... | 260,137        | 260,976        |
| Ingots .....   | 259,984        | 265,560        |
| Blooms .....   | 250,500        | 230,605        |
| Rails .....    | 123,830        | 144,108        |
| Rods .....     | 46,111         | 41,918         |

For the separate month of April the output was: Pig iron, 22,760 tons; ingots, 24,815 tons; blooms, 23,947 tons; rails, 12,836 tons; rods, 4,297 tons. Shipments for April were some 8,000 tons below March, which was the banner month in the company's history.

### APRIL OUTPUT, DOMINION COAL CO.

The output from the Dominion Coal Company's collieries last month amounted to 288,835 tons. This is the smallest April

output since 1905. Last month's output in detail was as follows:—

|                     |             |
|---------------------|-------------|
| Dominion No. 1..... | 51,240 tons |
| Dominion No. 2..... | 64,330 "    |
| Dominion No. 3..... | 24,407 "    |
| Dominion No. 4..... | 36,172 "    |
| Dominion No. 5..... | 45,851 "    |
| Dominion No. 6..... | 9,310 "     |
| Dominion No. 7..... | 14,762 "    |
| Dominion No. 8..... | 16,789 "    |
| Dominion No. 9..... | 25,974 "    |

|                 |           |
|-----------------|-----------|
| Total .....     | 288,835 " |
| Shipments ..... | 180,919 " |

### DOMINION COAL'S FOUR MONTHS' OUTPUT.

Dominion Coal's output for the first four months of the year is 946,000 tons, against 1,243,080 tons a year ago:—

|                    | 1909.   | 1908.     | 1907.     |
|--------------------|---------|-----------|-----------|
| January . . . . .  | 195,971 | 312,358   | 231,606   |
| February . . . . . | 206,970 | 283,358   | 225,716   |
| March . . . . .    | 251,585 | 344,129   | 310,220   |
| April . . . . .    | 291,934 | 303,249   | 316,384   |
| Totals . . . . .   | 946,570 | 1,243,094 | 1,083,926 |

#### NOVA SCOTIA STEEL AND COAL CO. OUTPUT.

The output of coal at the Nova Scotia Steel and Coal Company's collieries for the month of April was 500 tons greater than in the corresponding month last year. The output by the collieries was as follows:—

|                           |             |
|---------------------------|-------------|
| No. 1 . . . . .           | 20,540 tons |
| No. 2 . . . . .           | 4,011 "     |
| No. 3 . . . . .           | 20,637 "    |
| No. 4 . . . . .           | 2,522 "     |
| No. 5 . . . . .           | 12,011 "    |
| Total . . . . .           | 59,721 "    |
| Pig iron output . . . . . | 5,600 "     |
| Steel output . . . . .    | 6,600 "     |

#### CUMBERLAND COLLIERIES' OUTPUT.

Shipments for the month of April from the Cumberland Collieries, Springhill, were 34,435 tons.

#### COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt camp, and those from Jan. 1, 1909, to date:—

|                         | Week ending<br>April 24. | Since<br>Jan. 1. |
|-------------------------|--------------------------|------------------|
|                         | Ore in lbs.              | Ore in lbs.      |
| Crown Reserve . . . . . | 121,843                  | 1,781,119        |
| Kerr Lake . . . . .     | 60,000                   | 483,442          |
| La Rose . . . . .       | 261,300                  | 4,456,518        |
| Nipissing . . . . .     | 321,272                  | 3,831,572        |
| O'Brien . . . . .       | 128,598                  | 589,918          |
| Right of Way . . . . .  | 128,102                  | 1,205,672        |
| Temiskaming . . . . .   | 60,000                   | 710,200          |

Ore shipments to April 24, 1909, are 17,942,970 pounds, or 8,971 tons. Total shipments for week ending April 24, 1,081,115 pounds, or 540 tons.

|                            | Week ending<br>May 1. | Since<br>Jan. 1. |
|----------------------------|-----------------------|------------------|
|                            | Ore in lbs.           | Ore in lbs.      |
| Buffalo . . . . .          | 44,620                | 384,640          |

#### RAND GOLD OUTPUT.

The Rand gold output for April is estimated in London at 600,000 ounces, or 7,500 ounces less than March, being the smallest output, excepting the short month of February, since last September. Comparison of values is as follows:—

|                          |              |
|--------------------------|--------------|
| April, 1908 . . . . .    | \$12,017,000 |
| March, 1909 . . . . .    | 12,902,000   |
| February, 1909 . . . . . | 12,004,000   |
| January, 1909 . . . . .  | 13,064,000   |
| December, 1909 . . . . . | 14,031,000   |
| April, 1907 . . . . .    | 11,405,000   |
| April, 1906 . . . . .    | 9,329,000    |
| April, 1905 . . . . .    | 8,475,000    |
| April, 1904 . . . . .    | 6,497,000    |

#### MARKET REPORTS.

May 4.—Connellsville coke, f.o.b., ovens:—  
Furnace coke, prompt, \$1.40 to \$1.50.  
Foundry coke, prompt, \$1.80 to \$2.00.

##### Metals.

May 4.—Tin, Straits, 28.95 cents.  
Copper, prime Lake, 13 cents.  
Electrolytic copper, 12.70 cents.  
Copper wire, 14.25 cents.  
Lead, 4.20 to 4.22 1/2 cents.  
Spelter, 5.02 1/2 cents.  
Antimony, Cookson's, 8.25 cents.  
Aluminium, 22 to 24 cents.  
Nickel, 40 to 47 cents.  
Bismuth, \$1.75 per lb.  
Platinum, \$22.50 to \$23.50 per ounce.  
Quicksilver, \$44.50 to \$45.00 per 75 lb. flask.

# FOR SALE

Owing to having been replaced by larger equipment, we offer, subject to prior sale, the following equipment at genuine bargains:

6 New Return Tubular Boilers, 150 H. P., 125 lbs. working pressure.

1 Second Hand Return Tub. Boiler, 80 H. P., 60 lbs. working pressure.

2 Second Hand Return Tub. Boilers, 60 H. P., 60 lbs. working pressure.

5 Second Hand Locomotive Type Boilers, 150 H. P., 125 lbs. working pressure.

2 Second Hand Ingersoll Sergeant Class A straight line Air Compressors; Steam Cylinders 24" dia.; air cylinders 26 1/4" dia.; 30" stroke.

1 Second Hand Ingersoll Sergeant Class G Duplex Air Compressor; Steam Cylinders 18" dia.; L. P. Air Cylinders 28 1/4" dia.; H. P. Air Cylinders 17 1/4" dia.; 24" stroke.

1 Second Hand Four Wheel Saddle Tank Locomotive, 42" gauge, cylinders 10" x 14"; weight 14 tons.

4 Second Hand Jeffrey 10-ton Electric Mine Locomotives, gauge 36", 75 H. P.

1 New Aldrich-Westinghouse Portable Electric Mine Pump mounted, 36 gauge; capacity 100 gals.; 300' lift; 10 H. P., 220 volts D. C. Enclosed Motor.

1 Second Hand Danville Tail Rope Haulage Plant, Hoist 4 drums 88" dia., Double engines, Cylinders 20" x 36"

1 Second Hand Danville Endless Rope Haulage Plant, Hoist 2 drums 60" dia., Double Engines, Cylinders 10" x 18".

2 Second Hand Crocker Wheeler D. C. Generators 125 V, 200 Amp. 25 K. W.

1 Second Hand Marble Switch Board complete with Ammeters and volt meters.

1 Second Hand 80 H. P. McEwing High Speed Horizontal Engine.

1 Second Hand 40 H. P. McEwing High Speed Horizontal Engine.

3 Second Hand Lidgerwood-Jeffrey Electric Hoists, 220 V. direct current, 75 H. P.

1500 feet Second Hand 1" wire Haulage Rope, 6 strands, 7 wires, plough steel, in good condition.

10 tons 2 1/2" square soft steel—new.

400 Hadfields Steel Mine Car Wheels; 18" dia., 1 3/4" axle; bronze bushed.

**All Machinery in good Condition and will pass Closest Inspection. Immediate Shipment.**

FERNIE - - - B. C.

## Amatite ROOFING

Most roofings are made of only *one layer* but Amatite is made in *five layers*. The bottom layer is wool felt, the next is real Coal Tar Pitch, the third is wool felt, the fourth is pitch again, into which is embedded the fifth layer, namely, the *Mineral Surface*.

If the weather should, in the course of years, wear away the mineral surface and dispose of the layer of Pitch (which is the most

waterproof substance on earth) it would still have to penetrate a layer of felt and another layer of composition and another layer of felt before the roof would leak.

It is easy to see why Amatite lasts so long when you realize how it is made.

That mineral surface *requires no painting* or coating whatever and will take the brunt of the weather without renewal or attention or care.

Send for a sample of Amatite. It's free.

# Dominion Coal Company

Any person interested in the industrial life of Cape Breton or Canada, should have in his possession a copy of an illustrated volume entitled "Dominion Coal Co." by F. W. Gray. It contains 128 pages, giving a general description of mining and transportation.

The following are the subjects treated. General description of the Sydney coal fields: The mines of the Glace Bay Basin. The Phalen Seam, The Harbour Seam, The Emery Seam and lower seams of Glace Bay Basin, The Langan-Victoria areas, The fire-fighting organization and equipment, General and transportation. Every branch of work is illustrated and makes a splendid souvenir and historical volume. MacLeod's Bookstores at Sydney and Glace Bay are the local selling agents. Price \$1.00. The edition is limited all plates being destroyed.

CONTRACTORS TO ADMIRALTY, WAR OFFICE AND COLONIAL GOVERNMENTS

# Allan, Whyte & Co.

CLYDE PATENT WIRE ROPE WORKS

Rutherglen, Glasgow, Scotland

# WIRE ROPES

For Winding and Haulage in Collieries and Mines, Aerial Ropeways, Transmission of Power, Suspension Bridges, etc. SPECIALLY FLEXIBLE ROPES for Hoists, Winches, Loading and Discharging Cranes, Shipping Purposes, Towing, Alligator and Dredger Ropes, etc. SPECIAL ROPE FOR LOGGING.

Our Ropes are made from wire drawn for our exclusive use, and are at work all over Canada. Messrs. Nova Scotia Steel & Coal Co., Ltd., who use them largely, write that one of our haulage ropes at their Wabana Mine has been in use for **5 years**, drawing over 1,750,000 tons and still in good condition. From the Atlantic to the Pacific they are well known and our agents will be only too pleased to give all information to enquirers. They may be had from the following, viz:

Nova Scotia: Wm. Stairs, Son & Morrow, Limited. New Brunswick: W. H. Thorne & Co., Limited.  
Montreal and Toronto: Drummond, McCall & Co. Vancouver, B.C.: John Burns. Winnipeg: David Philip, Portage Ave.

HIGHEST Quality. MODERATE Price. Prompt Delivery. SATISFACTION in use.  
Cables: "Ropery, Rutherglen." Codes: A. B. C. (4th and 5th Editions), A.I., Liebers and Private.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

# Geological Survey

## PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects

### MARITIME PROVINCES

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

### QUEBEC

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the province north of the St. Lawrence are also available.

### ONTARIO

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

### THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

### BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

### YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

### THE NORTH-WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report and map will be sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to *THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.*

### THE FOLLOWING REPORTS AND MAPS HAVE BEEN ISSUED DURING THE PAST YEAR

- |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

University of Toronto**FACULTY OF APPLIED SCIENCE  
AND ENGINEERING**

## Courses in

1. Civil Engineering.
2. Mining Engineering.
3. Mechanical and Electrical Engineering.
4. Architecture.
5. Analytical and Applied Chemistry.
6. Chemical Engineering.

Diploma granted at the end of three year  
B. A. Sc. at the end of one additional year.

## Professional Degrees:

Civil Engineer (C. E.)  
Mining Engineer (M. E.)  
Mechanical Engineer (M. E.)  
Electrical Engineer (E. E.)  
Chemical Engineer (C.E.)

For Calendar and other information apply to the  
Secretary

A. T. LAING.

# Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,

**Toronto, Canada.**

# PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

## Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement.

The price of prospecting licenses is \$5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only \$2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, \$10.00 per acre, and on lands situate less than 20 miles from such a railway, \$20.00 per acre.

Superficial products and building materials are sold \$2 and \$4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed

lands; work must be bona fide begun within two years and \$500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of \$10.00 and a rent of \$1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts.

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

**The Hon. Minister of Colonization, Mines and Fisheries**  
Parliament Buildings, Quebec.

# A Handy Reference List

We urge you to examine the books listed below with great care. Some are brand new—all are standard. We can supply any technical book in print

## Copper

### Principles of Copper Smelting

BY EDWARD D. PETERS,  
*Professor of Metallurgy, Harvard University.*  
612 pages, 6x9; cloth. \$5.00 (21s.) postpaid.

### Modern Copper Smelting

BY EDWARD D. PETERS.  
640 pages, 6x9; cloth, \$5.00 (21s.) postpaid.

### Copper Mines of the World

BY WALTER HARVEY WEED.  
376 pages, 6x9; cloth, \$4.00 (17s.) postpaid.

### Notes on Lead and Copper Smelting and Copper

#### Converting

BY HIRAM W. HIXON.  
128 pages, 6x9. \$3.00 (12 6) postpaid.

#### Pyrite Smelting

BY T. A. RICKARD,  
Formerly Editor of THE ENGINEERING AND MINING JOURNAL.  
210 pages, 6x9. \$2.00 (8 6) postpaid.

#### Matte Smelting

BY HERBERT LANG.  
98 pages, 6x9. \$2.00 (8 6) postpaid.

## Lead and Zinc

### The Metallurgy of Lead

BY H. O. HOFMAN  
*Professor of Metallurgy, Massachusetts Institute of Technology.*  
600 pages, 6x9. \$6.00 (26s.) postpaid.

BOOKS BY WALTER RENTON INGALLS,  
Editor of THE ENGINEERING AND MINING JOURNAL.

### Lead and Zinc in the United States

6x9; cloth. \$4.00 (17s.) postpaid.  
(Price subject to change)

### The Metallurgy of Zinc and Cadmium

701 pages, 6x9; cloth. \$6.00 (25s.) postpaid.

### Lead Smelting and Refining

336 pages, 6x9; cloth. \$3.00 (12 6) postpaid.

### Production and Properties of Zinc

328 pages, 6x9; cloth. \$3.00 (12 6) postpaid.

## Gold and Silver

### The Chemistry of Cyanide Solutions

Resulting From the Treatment of Ores.

BY J. C. CLENNELL  
164 pages, 6x9 cloth, illustrated, \$2.50 (10 6) postpaid.

### Practical Notes on the Cyanide Process

BY FRANCIS L. BOSQUI, PH. B.  
*Superintendent of the Standard Consolidated Mining Company's Cyanide Works, Bodie, Cal.*  
201 pages, 5½x9, illustrated, \$2.50 (10 6) postpaid.

### Stamp Milling of Gold Ores

BY T. A. RICKARD.  
6x9; illustrated. \$2.50 (10 6) postpaid.

### Hydrometallurgy of Silver

BY OTTO KAR HOFMANN.  
336 pages, 6x9; cloth. \$4.00 (17s.) postpaid.

## Iron and Steel

### The Manufacture and Properties of Iron and Steel

BY HARRY HUSE CAMPBELL,  
*Metallurgical Engineer for the Pennsylvania Steel Company, etc.*  
Entirely revised in 1907. 641 pages; 6x9; illustrated.  
\$5.00 (21s.) postpaid.

### The Metallurgy of Iron and Steel

BY BRADLEY STOUTHON,  
*Adjunct Professor of Metallurgy, School of Mines, Columbia University.*  
Fully illustrated; 6x9. \$3.00 (12 6) postpaid.

### The Metallurgy of Steel

BY HENRY M. HOWE, A.M., S.B., L.L.D.  
9x12; fully illustrated. \$10 (42s.) postpaid.

## The Manual of Fire Assaying.

BY CHAS. H. FULTON  
176 pages, 6x9, illustrated. \$2.00 (8 6) postpaid.

Immediately upon its publication the leading assayers, metallurgists and professors of the country hailed this as the best work yet issued on the subject. It substitutes exact knowledge for the rule-of-thumb.

## Ore Dressing

BY ROBERT H. RICHARDS,  
*Professor of Mining, Massachusetts Institute of Technology.*  
Two volumes. 6x9; cloth, 1250 pages. Profusely illustrated. Per set, \$10.00 (42s.) postpaid.

The standard authority on all classes of ore dressing by one of the leading mining authorities of the world.

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver; \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Minerals; or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579,039 the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 100,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

## Our Analyses Speak for Themselves.

HAS. SIMISTER,  
General Superintendent.

J. D. HURD,  
General Manager.

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

W. W. CORY, Deputy of the Minister of the Interior

## Canadian Pacific Railway

for its excellent equipment. All are pleased with the bright, modern coaches; the exceptionally roomy berths in the sleeping cars; superior dining car service, etc.

The "good cars" bring the C. P.R. hundreds of passengers every week.

All equipment is built in the Angus Shops at Montreal from the most modern designs, embodying every improvement known to practical railroading.

**R. L. THOMPSON, District Passenger Agent, - - Toronto**

# Behrend Concentration System

## Combination WET and DRY

A complete recovery from all slimes and minerals such as Graphite, Galena, Stibnite, Chalcopyrite, Tetrahedrite, Sylvanite, Molybdenite, Stephanite, Argentite, Ruby Silver and Native Silver.

This system will make low grade deposits pay. Every mine having an eye to business should investigate this system which has the approval of leading mining authorities.

A completely equipped plant, including concentrators, crushers, rolls, etc., for testing purposes is located at address below. Forward a sample of your ore for preliminary test.

## Behrend Concentrators, Limited

48 Inspector Street, Montreal

## UNDERWOOD

300 Underwoods are made every working day. It is the largest output of any typewriter factory in the world.

The public would not take that output, and more if they could get it, if any other typewriter would give them as good service. The Underwood is not the cheapest in price but it is the cheapest in service. If you pay less you get less—a great deal less. The typewriter is cheap that gives you the best service, no matter what it costs. In this sense the Underwood is cheap.

## Springhill Coal

### The Cumberland Railway & Coal Co.

Are prepared to deliver this well known  
Steam Coal at all points on the lines of  
G. T. R., C. P. R., and I. C. Railway  
and connections.

### HEAD OFFICE

80 St. Francois Xavier Street, Montreal

Address P.O. Box 196

## RAMPART CEMENT

Perfectly Sound. Never swells or bursts.  
Reliable for all purposes for which hydraulic  
cement is used.  
Fineness 92 per cent. through a 200 mesh  
sieve.

Strength up to standard specification and  
permanent.

Used by the leading Mining Companies of  
the Maritime Provinces.

### Sydney Cement Co., Ltd.

## ORE AND ROCK CRUSHERS

We have a complete knowledge of Rock Crushing and Crushers gained through many years of Crusher Building and Study.

You need this information! It will be of value to you in any Crushing Proposition and is yours for the asking.

The Farrel-Bacon Rock and Ore Crusher is used extensively by the larger mining companies and by many of the Principal American Railroads for Crushing Ballast.

It was adopted by them after careful study of all other types and exhaustive tests.

Our Crusher Catalogue contains more information. May we send it?

### GOVERNMENT ASSISTANCE FOR NOVA SCOTIAN GOLD MINES.

In the last hours of the recent session of the Legislature of Nova Scotia an important measure became law. The 25th day of April, 1909, should henceforth be memorable, for on that date an Act was passed authorizing the Governor-in-Council to assist in further development of gold mines, and to give aid towards the development of water power in order to reduce the cost of gold mining in the Province.

The Act, officially entitled "An Act for the further assisting of the Gold Mining Industry," consists of five short sections. The first of these sections empowers the Governor-in-Council to give reasonable assistance in the operations of cross-cutting at such depths and for such distances as may be approved by the Inspector of Mines or an engineer selected by the Department of Mines.

The second section authorizes the Governor-in-Council to utilize such water-powers as may reduce the cost of gold mining in Nova Scotia. This is subject to the approval of the Inspector of Mines, or of an engineer selected by the Department of Mines.

The third section empowers the Governor-in-Council to refer the location of shafts, winzes, cross-cuts and levels to the approval of the Inspector of Mines, or to the approval of an engineer selected by the Department of Mines.

The fourth section intimates that payments are to be made on the monthly progress reports made by the Inspector of Mines, or by an engineer selected by the Department of Mines.

The fifth, and last, section provides that any individual, company, or association; receiving assistance under this Act shall pay the Government a royalty on all gold ore from the property or mines upon it in respect to which Government money has been expended, the sum of three per cent. on the gross amount of such gold so won, and such royalty shall continue to be paid by such individual, company or association, until the full amount advanced by the Government has been repaid. All such loans made, or assistance given, shall not be a charge against the property, company, individual, or association, but against the gold won from such property receiving assistance under this Act.

This, then, is the tenor of the Act that is designed to revivify gold mining in Nova Scotia. Its provisions, undoubtedly, are broad and wise. The Act itself is succinct and definite. But the miner who takes advantage of its provisions will find himself at the mercy of those who must interpret the Act. Even at the worst, there is ample encouragement left for the prospector and the casual miner. In its constructive phases the

new Act is a wonderful and almost unique encouragement to outside investors. All Canada will rejoice if Nova Scotia progresses in proportion to her resources.

### CONCENTRATING AND SMELTING COBALT ORES.

The annual report of Mr. A. A. Cole, mining engineer to the Temiskaming and Northern Ontario Railway Commission, has just been received. An abstract of this instructive pamphlet appears elsewhere in this issue. It will be noticed that detailed information concerning smelting rates has been gathered by Mr. Cole. One or two points call for notice.

During the year 1908, ten reduction companies treated ores from Cobalt. Four of these were Canadian concerns. To these four smelters 7,401.14 tons of high-grade ore were shipped. This quantity was equivalent to 29.18 per cent. of the total tonnage of the camp. In value the ore treated in Canada largely exceeded that of all the ore shipped out of the country. The great bulk of foreign shipments were low-grade.

Comparison of Canadian with foreign tariff rates does not reflect unfavorably upon the former. The most liberal smelting tariff is that of a Canadian enterprise. Apparently the metallurgical methods (carefully guarded secrets) of our own smelters are quite as effective as those of other countries.

This is all very satisfactory. But is there any just and sufficient reason why all the ore that comes from Cobalt should not be smelted in Canada?

Six concentrating mills are now in operation in Cobalt. Four more are under construction and will be running before the end of the current year. The flow-sheets of the mills that are now working indicate that the methods of comminution and preliminary concentration are becoming standardized. In three of these plants crushers, rolls, trommels, and jigs constitute the first four units. In five plants jigs are installed. In three mills (not including the McKinley-Darragh, which is nearing completion) stamps follow the jigs. Only one flow-sheet includes the Chilian mill.

It would appear that the probable arrangement of units in mills yet to be designed will conform to the following scheme: Crushers, rolls, trommels, jigs, stamps. The treatment of the stamp products after classification will always vary within certain limits. The choice of tables for sands and slimes depends largely upon the experience and predilections of the mill superintendent.

Two tube mills and one cyanide plant are in use. The future will see a large increase in these units.

### THE EIGHT HOURS DAY.

English, Welsh, and Scotch colliery operators are looking forward with misgivings to July 1st, the day on which the coal miners' Eight Hours Act becomes operative. The operators believe that an immediate

reduction in output will be the first effect of this limitation of working hours below ground. They contend that this reduction will amount to at least 10 per cent. and, in many instances, 20 per cent. The argument advanced by the supporters of the Act, to the effect that shorter hours will inspire the miners to keener and more continuous effort, is met by the assertion that in a vast majority of the collieries a maximum of work is already obtained and that, in any case, the miners' expenditure of energy cannot be intensified by an Act of Parliament.

The extent to which existing plants will require to be modified in order to meet the demand for speedier haulage, winding, and coal-winning, is a serious question. It appears probable that not a few mines, especially those whose equipment is antiquated, will not survive the change.

One clause of the Act is to be a storm centre. Section 3, clause 1, permits an addition of one hour to the working day on sixty days of the year. The questions as to how these nine-hour days are to be distributed, and as to whether the extra hour will be considered as overtime or not, have yet to be discussed.

Meanwhile the Miners' Federation has declared itself ready to fight to the last ditch against any reduction in wages.

As July 1 approaches, new difficulties crop up with disturbing rapidity. The most encouraging feature of the situation is the fact that the leaders of the Miners' Federation are capable and earnest men, not mere demagogues. Moreover, in Great Britain, as in most other parts of the British Empire, arbitration is becoming a habit.

We shall venture upon no prophecy. But we shall await, not without trepidation, the introduction of the eight hours day.

### PETROLEUM AND OILS.

Mr. Eugene Coste has constituted himself champion of the inorganic origin of petroleum. This implies not a small amount of moral courage. But Mr. Coste is courageous if nothing else.

Somehow we are led to believe that there may be a faint adumbration of truth in what Mr. Coste tells us. This is rank heresy; we only talk it in confidence. But it is obvious to the amateur that all advocates of the organic origin of petroleum must be apologists. Mr. Coste is not an apologist. He is an out and out enthusiast. His facts and arguments are set forth in battle array. He is afraid of no man.

### GOLD MINING IN RHODESIA IN 1908.

Fourteen years ago, Rhodesia contributed nothing to the world's production of gold. Now it ranks sixth amongst gold-producing countries. Last year its gold yield was 606,962 fine ounces, valued at £2,526,007. This exceeded the yield for 1907 by 15.4 per cent. The

tonnage of ore crushed was 1,819,230 tons, giving an average of 27.77 shillings per ton. Up to the end of 1908, Rhodesia's total output of gold amounted to 3,208,789 ounces, valued at £11,831,526.

This, in bald figures, is the history of Rhodesia's remarkable progress. Its growth has not been unmarked by difficulties, reverses and discouragements. At present, however, Rhodesian gold mining appears to be established beyond a peradventure.

During the year 1908 the producers contributing to the output numbered 446, as compared with 275 in 1907. Of this total, 28 companies produced more than half the gold reported. One hundred and one tributors and 293 small workers were responsible for the rest. Upon the last class devolved almost all the prospecting done during the year.

### NEW QUEBEC MINING BILL.

A new mining bill was introduced into the Quebec Legislature on Saturday, May 8th. It consisted mainly of amendments to the present Mining Act. The chief amendments are easily outlined. One was designed to extend the time within which an exploitation permit must be taken out. Another increases the penalty for pulling up stakes placed around concessions applied for. This penalty is increased from \$10 to \$25, with an alternative of one month's imprisonment. The third provision restricts the powers of the Governor-in-Council in connection with mining concessions. It withdraws his prerogative to fix and increase the price of mining concessions.

The bill is healthy in tone. It met the approval of both the Government supporters and the Opposition.

## COBALT IN 1908.

Abstract of Report of Arthur A. Cole, Mining Engineer  
for Cobalt District, for Calendar Year 1908.

The approximate production of the world, the United States and Cobalt for the year 1908 is as follows:—

World's production of silver for 1908, 194,000,000 ozs.

United States production of silver for 1908, 51,798,053 ozs.

Cobalt's production of silver for 1908, 18,000,000 ozs.

It will thus be seen that Cobalt supplied over 9 per cent. of the world's production during 1908.

The following tabulation illustrates the advance that Canada has made as a silver producing country, the advance in great part being due to the Cobalt production.

| Country.            | 1906             | 1907             | 1908             |
|---------------------|------------------|------------------|------------------|
| Mexico . . . . .    | 68,500,000 ozs.  | 65,600,000 ozs.  | 69,000,000 ozs.  |
| United States . . . | 56,517,900 ozs.  | 58,850,615 ozs.  | 51,798,053 ozs.  |
| Australasia . . . . | 13,519,410 ozs.  | 17,516,433 ozs.  | ..... ozs.       |
| Germany . . . . .   | 11,649,160 ozs.  | 12,439,896 ozs.  | ..... ozs.       |
| Canada . . . . .    | 8,568,685 ozs.   | 12,750,004 ozs.  | 21,000,000 ozs.  |
| World's prod'n      | 184,552,343 ozs. | 193,542,381 ozs. | 194,000,000 ozs. |

The above figures for 1906 and 1907 were obtained from the Mineral Industry, while those for 1908 are estimated.

Canada thus takes fifth place in 1906, fourth place in 1907, and probably third place in 1908.

The following values are given by the Ontario Bureau of Mines for the shipments from the Cobalt district for 1904, 1905, 1906 and 1907. The value for 1908 is estimated.

|                            |               |
|----------------------------|---------------|
| 1904 . . . . .             | \$ 136,217 00 |
| 1905 . . . . .             | 1,485,570 00  |
| 1906 . . . . .             | 3,573,908 00  |
| 1907 . . . . .             | 6,155,391 00  |
| 1908 (estimated) . . . . . | 9,000,000 00  |

Total . . . . . \$20,351,086 00

The outputs for 1907 and 1908 were distributed for treatment as follows:—

| Country                 | 1907      |        | 1908      |        |
|-------------------------|-----------|--------|-----------|--------|
|                         | Tons      | %      | Tons      | %      |
| Canada . . . . .        | 2,585.05  | 17.40  | 7,401.14  | 29.18  |
| Great Britain . . . . . | 167.13    | 1.13   | 222.08    | .88    |
| Germany . . . . .       | .....     | .....  | 229.46    | 1.18   |
| United States . . . . . | 12,098.95 | 81.47  | 17,439.42 | 68.76  |
| Total . . . . .         | 14,851.34 | 100.00 | 23,362.10 | 100.00 |

Almost all the ore treated in Canada was high grade, so that while the tonnage was less than one-third of the total, the value was greater than that of all the ore shipped out of the country.

### Silver.

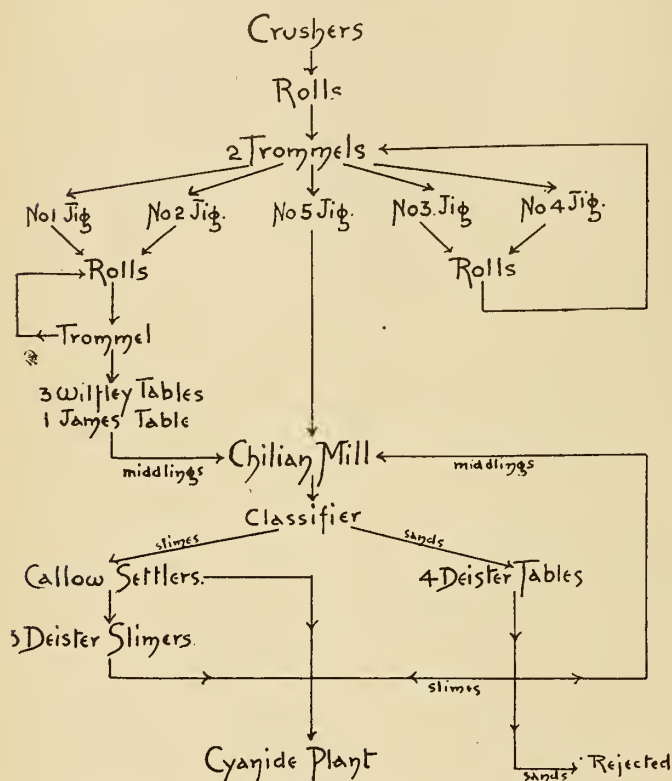

A disappointing feature of the year from the silver mining standpoint has been the continued depression in the price of silver. Towards the close of 1907 the price of silver fell rapidly and 1908 was marked by an almost continued decline. The maximum price was that of 7th of January, 58¾ cents, the minimum being 47½ cents, on the 2nd December. The average price for the year was 52.864, or nearly 12½ cents below the average price for 1907.

The average price by months in cents per fine ounce, at New York, was as follows:—

|                    |        |                     |        |
|--------------------|--------|---------------------|--------|
| January . . . . .  | 55.678 | July . . . . .      | 53.115 |
| February . . . . . | 56.000 | August . . . . .    | 51.683 |
| March . . . . .    | 55.365 | September . . . . . | 51.720 |
| April . . . . .    | 54.565 | October . . . . .   | 51.431 |
| May . . . . .      | 52.795 | November . . . . .  | 49.647 |
| June . . . . .     | 53.663 | December . . . . .  | 48.769 |

The causes for the low price of silver were varied. The almost universal business depression caused a large falling off in the demand for silver in the arts. Another powerful factor was the unrest in the market of

Flow Sheet, Buffalo Concentrator.

the far east, China and India, at times, offering silver while they are usually consistently heavy buyers.

The production of silver in the United States is made in connection with that of lead, copper and other metals. Silver is thus a by-product, and as such its production is not likely to be affected materially by the low price of silver. In Mexico it costs 40 cents per ounce to produce refined silver, so that at the present price the margin of profit is very small. This accounts for the closing down of some of the Mexican mines lately.

In Cobalt the cost of production in the principal mines is under 20 cents per ounce. This is one of the reasons why Cobalt's output has continued to rise even in the face of a falling market.

#### Cobalt.

Cobalt is seldom seen in the metallic state as it is marketed exclusively in the form of oxide. Throughout 1907 the oxide sold for \$2.50 per pound. In March of 1908 a violent rate war caused the price to be cut at frequent intervals until on April 1st it was \$1.45 per pound, a reduction of \$1.05 in a few weeks.

The world's annual consumption of cobalt is about 300 tons. On account of the restricted market and the large production in the Cobalt district, the marketing of Cobalt ores for the cobalt contents has been difficult. The Anglo-French Nickel Co., of Swansea, Wales, came in to the market for a carload of ore from time to time as the demand warranted it.

In the early part of 1908 this company paid the following prices for cobalt:—

- 8 to 10 per cent. cobalt, 35c per pound, Cobalt.
- 10 to 12 per cent. cobalt, 40c per pound, Cobalt.
- 12.1 to 14 per cent. cobalt, 45c per pound, Cobalt.
- 14.1 to 16 per cent. cobalt, 50c per pound, Cobalt.
- 16 per cent. or over, cobalt, 55c per pound, Cobalt.

After April the prices offered were 10 cents per pound lower than above, and at the end of the year they were out of the market entirely. There is ever likelihood that the next price offered will be still lower.

The Canadian Copper Co. and the Deloro Mining and Reduction Company each pays for cobalt in ore when it goes 6 per cent. or over, providing that the nickel contents are lower than the cobalt contents.

#### Arsenic.

For a time one smelting company did pay a small amount for arsenic, but this has been cut out of the latest schedule, so that no arsenic is now paid for, though several smelting companies save, refine and market as a by-product in the form of white arsenic.

#### Nickel.

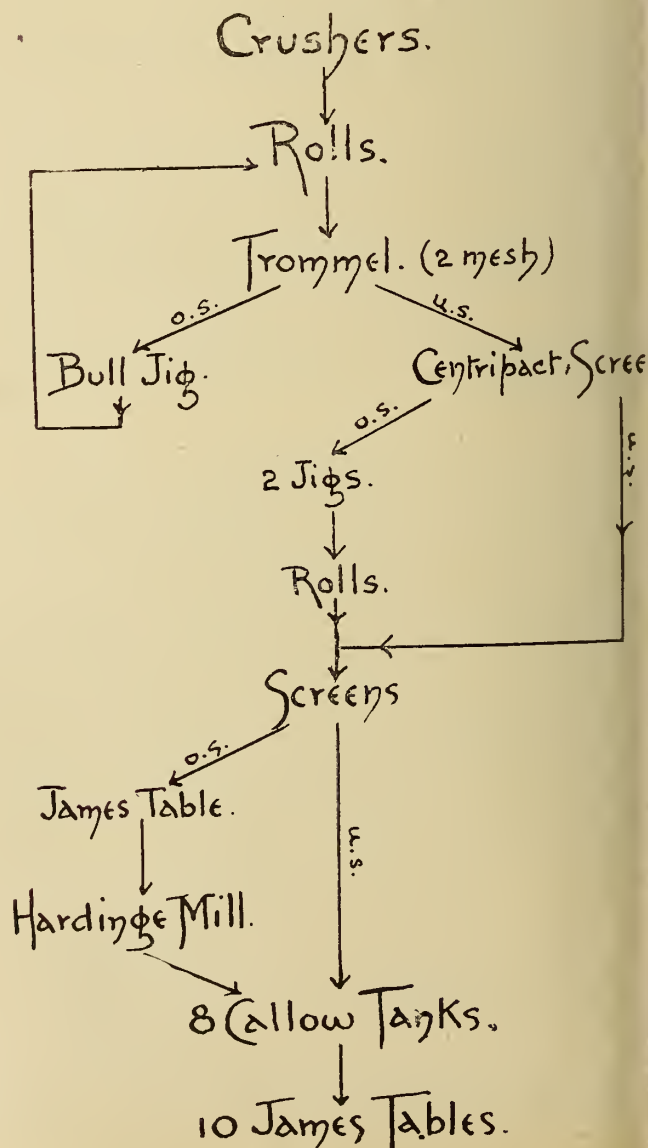

Up to the present nickel contents of ores from Cobalt have been considered more of a detriment than otherwise.

#### Smelting.

The following smelting companies have received and treated ore from Cobalt during 1908.

1. Anglo-French Nickel Company, Swansea, Wales.
2. American Smelting & Refining Co., Perth Amboy, N.J., Denver, Col.

Flow Sheet, Cobalt Central Concentrator.

3. Balbach Smelting & Refining Co., Newark, N.J.
4. Beer, Sondheimer Co., Hamburg, Germany.
5. Canadian Copper Co., Copper Cliff, Ont.
6. Coniagas Reduction Company of Canada, Orford, Ont.
7. Consolidated Mining & Smelting Co., Trail, B.C.
8. Deloro Mining & Reduction Co., Deloro, Ont.
9. Pennsylvania Smelting Company, Carnegie, Pa.
10. The United States Metal & Refining Co., Chrome, N.J.

#### 1. Anglo-French Nickel Company, Swansea, Wales.

The prices paid by this company for cobalt ores are given under the heading "Cobalt." Payment was made for the cobalt contents and no allowance was made for the silver values in the ore purchased.

#### 2. American Smelting & Refining Co., New York.

This company received ores from Cobalt at its plants at Perth Amboy, N.J., and Denver, Col. The schedule offered was as follows:—

Payment.—Forty-five days after date of sampling. If a mine is willing to contract for a total year's output or 1,000 tons, the following schedule is offered:

#### For Ores Under 1,500 Ounces and Over 60 Ounces.

Silver.—Pay for 95% of the silver contents at the New York quotations.

Treatment Charge.—\$7.00 per ton of 2,000 pounds, dry weight; in case of cash settlement the treatment charge is \$7.50 per ton.

No payment for cobalt or nickel.

No penalties for insoluble.

Arsenic.—An addition to the working charge will be made at the rate of 25 cents per dry ton for each per cent. of arsenic in excess of 5 per cent.

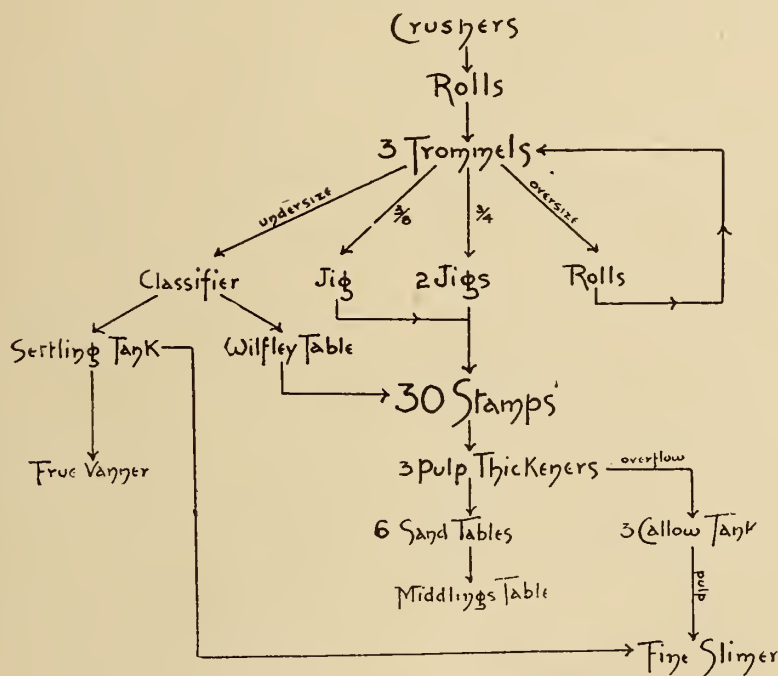

Payment.—Payment forty-five days after agreement of assays.

The freight from Cobalt to Perth Amboy, N.J.

#### 3. Balbach Smelting & Refining Co., Newark, N.J.

This company only entered the market occasionally,

Flow Sheet, Coniagas Concentrator.

#### For Ores Assaying 1,500 Ounces or Over per Ton.

Silver.—Pay for 94% of the silver contents at the New York quotations.

Treatment Charge.—\$10.00 per ton of 2,000 pounds, dry weight, plus one-half cent on each ounce of silver contained.

Arsenic.—An addition to the working charge will be made at the rate of 25 cents per dry ton for each per cent. of arsenic in excess of 5 per cent. Sampling free.

Payment.—Thirty days after agreement of assays.

#### For Ores Under 1,500 Ounces and Over 60 Ounces per Ton.

Silver.—Payment for 93% of the silver contents at the New York quotations.

Treatment Charge.—\$9.00 per ton of 2,000 pounds, dry weight, plus one-half cent on each ounce of silver contained.

Arsenic.—An addition to the working charge will be made at the rate of 25 cents per dry ton, for each per cent. of arsenic in excess of 5 per cent.

and had no standing schedule. The ore purchased was high grade.

#### 4. Beer, Sondheimer Co., of Hamburg, Germany.

This German company purchased high-grade ore in the Cobalt camp on the following schedule:—

Silver.—Pay for 94% of silver assay.

Treatment Charge.—\$44.00 smelting charge per dry ton.

Freight.—\$10.00 freight guarantee per gross ton. Beer, Sondheimer to supply barrels free of charge, suitable for transporting the ores.

Payment.—70% paid immediately against Ledoux & Co.'s assays. 30% paid three days after settlement of assays of Dr. Fred Claudet, of the Bank of England. Interest at 6 per cent. (6%) till due date. Dr. Claudet's expenses to be paid by Beer, Sondheimer & Co.

#### Canadian Copper Co., Copper Cliff, Ontario.

All purchases of Cobalt ores are made through the Orford Copper Co., of New York. The purchasing schedule was as follows:—

## Purchaser to make payment for:—

|          | % silver per ton ore when same assays | 100 oz. ag. and over. |
|----------|---------------------------------------|-----------------------|
| 75 %     | " " "                                 | 200 " "               |
| 84 %     | " " "                                 | 300 " "               |

|                                        |                      |
|----------------------------------------|----------------------|
| \$10 per ton of ore when same contains | 6% cobalt and over.  |
| \$20 per ton of ore when same contains | 8% cobalt and over.  |
| \$30 per ton of ore when same contains | 12% cobalt and over. |

No payment will be made for cobalt in ores containing less than 6% cobalt, nor in which the nickel contents are greater than the cobalt contents. Further, purchaser reserves the right to return, at shipper's expense, any such ores (i.e., nickel contents higher than cobalt contents) received at Copper Cliff.

as is due the seller in settlement upon these dates, such delivery to be made in New York City.

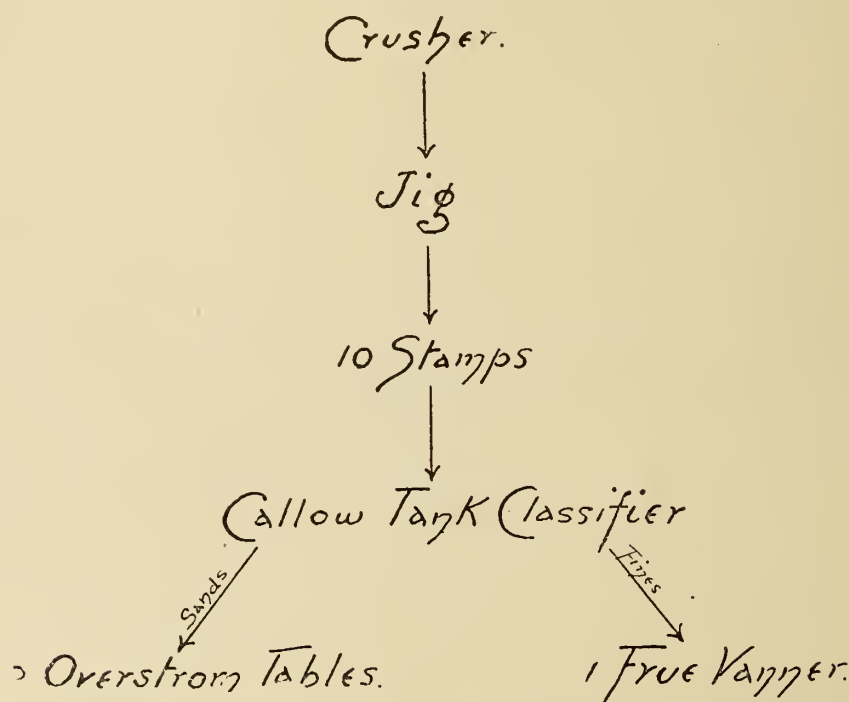

Payment for cobalt will be made as per the above scale when the cobalt content of the ore comes within the specifications mentioned, settlement for same to be made on the first due date for silver, namely, in 35 days after completion of sampling of ore.

Purchaser has named a rate of 75% silver return to the shipper on ore running from 100 to 200 ounces per ton of 2,000 pounds. This is to be considered as a penalty clause, and to apply in such cases where ores under 200 ounces have been shipped by mistake. Purchaser does not agree to accept regular shipments of ore which run less than 200 ounces of silver per ton of 2,000 pounds.

All purchases of these ores are made strictly subject to the following force majeure agreement:—

"If, by reason of the acts of God, strikes or other causes beyond control of either parties hereto, which may legally be called force majeure, either of them shall

Flow Sheet, King Edward Concentrator.

Ore to be delivered by seller to the Canadian Copper Co., f.o.b. cars, Copper Cliff, Ont. Ore to be at shipper's risk until sampling is undertaken, as purchaser can assume no responsibility for the ore until same has been taken into its sampler.

Purchaser to sample at its expense, purchaser's and seller's representatives to be present. Assays to be made by Ledoux & Co., of New York, at seller's expense, which assays are to govern in settlement.

Payment of 70% of the silver returnable to the seller, as per the above scale, to be made at the New York official price for silver on the first settlement date, which shall be 35 days after the date on which sampling of the ore is completed, and the balance, 30 per cent., on the second settlement date, on the New York official price of silver on that day, which shall be 90 days after sampling of the ore is completed. The purchaser, however, reserves the right to deliver upon either or both of the settlement dates above specified, in lieu of cash, at its option, such silver bullion (commercial bar silver)

be unable to carry out the conditions of this agreement as to shipment, receipt or treatment of consignments this agreement shall be suspended as long as this condition shall continue and the term of this agreement shall then be extended for such a period as shall be equivalent to the time of delay or interruption."

Further, this clause shall also cover unavoidable or extraordinary delays should they occur when the speis or silver bullion resultant from the smelting and treatment of these ores is in transit between Copper Cliff and Camden plants of the purchaser and between either of the above plants and the silver refinery of the Babcock Smelting Co., Newark, N.J.

#### 6. Coniagas Reduction Co., Limited, of Thorold, Ont.

Up to the present time the only ore treated by this smelter came from the Coniagas mine. It is likely, however, that custom smelting will be started during 1909.

The following is an extract from the 1908 report of the Coniagas Mines, Limited:—

"The works at Thorold are now handling the product of your mine (the Coniagas), and are running commercially as regards the production of refined silver and refined white arsenic, and we expect to place refined cobalt, oxide, and nickel oxide on the market very shortly, thus refining and marketing all the valuable constituents of your ores by a process which is confidently expected to yield a substantial profit."

**The Consolidated Mining & Smelting Co., of Canada, Trail, B.C.**

This smelting company has so far only purchased several test carload lots.

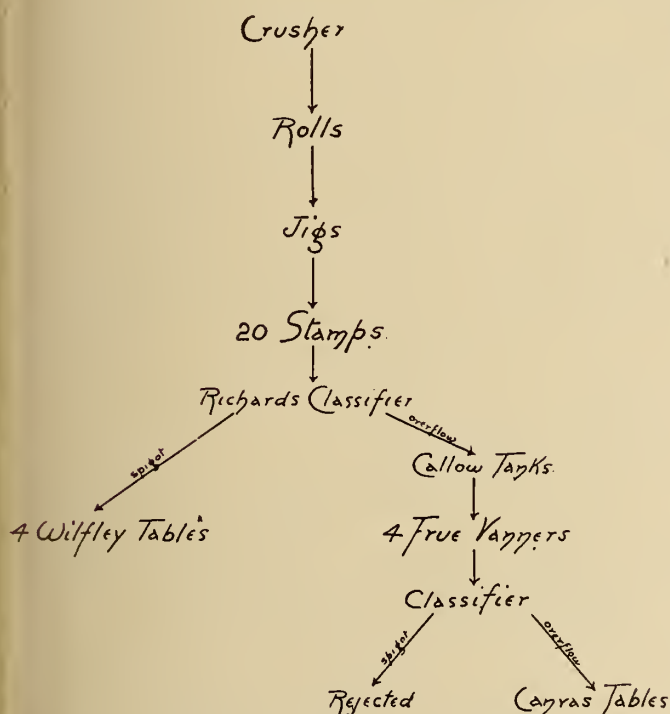

**8. Deloro Mining & Reduction Co., Deloro, Ont.**

Tariff on Cobalt Silver Ores and Concentrates.

Silver.—Pay for 98% of silver contents.

Treatment Charge.—\$20.00 per ton of ore and a refining charge of one cent per ounce of silver contained.

Flow Sheet, Northern Customs Concentrator.

Terms of Payment.—75% of net proceeds at New York quotation 30 days after completion of sampling. 25% of net proceeds at New York quotation 90 days after completion of sampling.

Cobalt.—On ore containing 6% and over, 10 cents per pound for cobalt contained. No payment will be made for cobalt in ores containing more nickel than cobalt. Payment for cobalt to be made with the second payment of silver. Ledoux & Co.'s assays accepted with the usual provisions as to umpire assays in case of unusual differences. Above assays to be made at shipper's expense. No charge for sampling. Ore to be delivered in carload lots f.o.b., Marmora Station, C. O. R. This tariff is subject to change without notice.

**9. Pennsylvania Smelting Co., Pittsburg, Pa., Works at Carnegie, Pa.**

Ores from Cobalt ranging from 50 ounces to 500 ounces per ton are purchased by the Pennsylvania Smelting Co. on the following schedules:—

Silver.—Pay for 95% silver, less one cent per ounce.

Treatment Charge.—\$9.00 per ton. Settling price, average for 20 days following date of arrival. No payment for cobalt or nickel. The freight rate from Cobalt to Carnegie, Pa., is \$8.80 per ton.

**10. United States Metal and Refining Co., Chrome, N.J.**

This company only bought an occasional carload of high-grade ore on special quotations.

**Concentration.**

Concentration now takes a very important position in the district's development. Undoubtedly in some instances the shipments to the smelters are smaller than formerly, due to the reduction of tonnage by concentration, nevertheless in most cases the tonnage is increased by the amount of the concentrates, as the ore treated is of such a low grade that it could not stand the freight and treatment charges without concentration.

Six mills are now in successful operation in the camp, and four more are under construction.

They belong to the following companies:—

1. The Buffalo Mines Company, Limited.
2. The Standard Cobalt Mines, Limited (Cobalt Central).
3. The Coniagas Mines, Limited.
4. King Edward Cobalt Silver Mines.
5. The Northern Customs Concentrators, Limited (formerly Muggley).
6. Nipissing Reduction Company.
- Under construction:—
7. Colonial Mining Company.
8. McKinley-Darragh-Savage Mines of Cobalt, Ltd.
9. Nova Scotia Mining Company.
10. O'Brien Mine.

The following table gives the tonnage of ore milled, the concentrates made, and the concentration ratio for the mills during 1908:—

**Concentration in Cobalt for 1908.**

| Mill.                                | Mines               | Ore milled Tons | Concentrates Tons | Concentration Ratio |
|--------------------------------------|---------------------|-----------------|-------------------|---------------------|
| 1. Buffalo.....                      | Buffalo .....       | 10,200          | 251.00            | 40—1                |
| 2. Cobalt Central....                | Bailey .....        | 4,246           | 97.15             | 44—1                |
|                                      | Big Pete .....      | 9,163           | 143.90            | 64—1                |
|                                      | Crown Reserve ....  | 669             | 15.22             | 44—1                |
| 3. Coniagas .....                    | Coniagas .....      | 13,605          | 304.00            | 45—1                |
| 4. King Edward....                   | King Edward .....   | 1,043           | 21.35             | 38—1                |
| 5. McKinley-Darragh (Old Mill).....  | McKinley - Darragh  | 450             | 20.00             | 28—1                |
| 6. Northern Customs Concentrator.... | City of Cobalt .... | 2,194           | 50.61             | 43—1                |
|                                      | Cobalt Townsite ... | 1,000           | 31.03             | 32—1                |
|                                      | Right of Way .....  | 1,500           | 36.46             | 41—1                |
|                                      | Silver Queen .....  | 3,253           | 70.63             | 46—1                |
| 7. Nipissing Red. Co.                | Foster .....        | 85              | 10.00             | 9—1                 |
|                                      | King Edward .....   | 40              | 1.50              | 27—1                |
|                                      | Kipissing .....     | 1,950           | 40.00             | 49—1                |
|                                      | Silver Lead .....   | 35              | 1.00              | 35—1                |
| Totals .....                         |                     | 49,424          | 1,093.85          | 45—1                |

At the mines without mills the grade of ore is raised by cobbing, washing and handpicking. The ore is usually first passed over a grizzly or coarse screen, as the screenings generally carry enough values to be of shipping grade without further treatment. At the Crown Reserve and Trethewey mines jigs are used in addition to the hand-picking.

With the smelter schedules and freight rates at present in force an ore must run about 45 ounces per ton to pay charges outside of the cost of mining. All ores below this point must therefore be concentrated if they

are to be shipped. The point at which the combined concentration and smelting rates meet the direct smelting rates is about 90 ounces. If, however, a mine owns its own mill the grade of ore that can be concentrated more profitably before shipping to the smelter direct is much higher. In the future, if present conditions hold, it will be natural to expect that very little ore will be shipped from the camp that will assay less than 100 ounces per ton.

In the following mill flow sheets all the smaller details have been cut out, leaving only the main working features.

The flow sheet of the Colonial Mill is to be similar to that of the King Edward.

The Northern Customs Concentrators, Limited, (formerly the Muggley Concentrator) and the Nipissing Reduction Company are custom mills, while the Cobalt Central Mill accepts some custom work, as well as the treatment of ores from the Cobalt Central mines.

The Northern Customs Concentrators, Limited, is now treating ores on the following contract schedule:—

by the Temiskaming and Northern Ontario Railway Commission:—

1. City of Cobalt Mining Company.
2. Cobalt Townsite Mining Company.
3. Nancy Helen Mines, Limited.
4. Railway Reserve Mines, Limited.
5. Right of Way Mining Company.
6. Wright Mining Company.
7. Jack Pot Silver Mining Company.
8. Cobalt Station Grounds Mining Company.
9. Ontario Development and Mining Co., Limited.

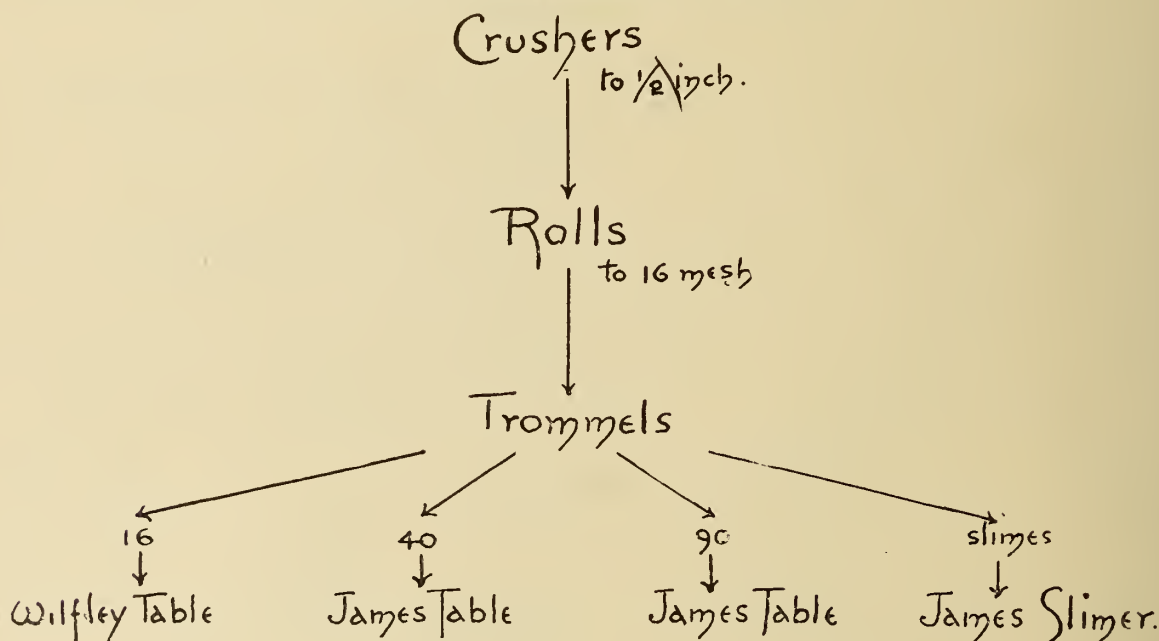

#### 1. City of Cobalt Mining Company.

The following was the underground development work done by this company during 1908:

|                              |             |
|------------------------------|-------------|
| Sinking .....                | 136 feet    |
| Drifting and crosscutting... | 1,935 feet. |
| Stoping .....                | 77,850 feet |

During the summer a new compressor plant was installed.

Flow Sheet, Nipissing Reduction Co. Concentrator.

On ore yielding less than 20 ounces silver per ton crushed, retain 10 ounces and return balance with 50 per cent. of other metals that can be sold.

|                             |              |
|-----------------------------|--------------|
| 20 to 40 ounces silver pay  | 55 per cent. |
| 40 to 60 ounces silver pay  | 60 per cent. |
| 60 to 80 ounces silver pay  | 65 per cent. |
| 80 to 100 ounces silver pay | 70 per cent. |

The Nipissing Reduction Company will treat ores on a flat rate of \$3.00 per ton or on the following percentage basis.

For ores assaying when received at the mill,

|                              |                             |
|------------------------------|-----------------------------|
| 20 to 40 ounces silver pay   | 50 per cent. silver values. |
| 40 to 60 ounces silver pay   | 55 per cent. silver values. |
| 60 to 80 ounces silver pay   | 60 per cent. silver values. |
| 80 to 100 ounces silver pay  | 65 per cent. silver values. |
| 100 to 150 ounces silver pay | 68 per cent. silver values. |

#### Leases.

During 1908 the following mining companies operated on a royalty basis on mineral lands owned and leased

#### 2. Cobalt Townsite Mining Company.

The development for 1908 consisted of:—

|                    |                  |
|--------------------|------------------|
| Sinking .....      | 158 feet         |
| Crosscutting ..... | 249 feet         |
| Drifting .....     | 712 feet         |
| Raising .....      | 104 feet         |
| Stoping .....      | 5,021 cubic feet |

#### 3. Nancy Helen Mines, Limited.

The total underground development work on this property at the end of the year 1908 consisted of:—

|                    |           |
|--------------------|-----------|
| Drifting .....     | 357 feet. |
| Crosscutting ..... | 274 feet. |
| Shaft .....        | 155 feet  |

and considerable stoping.

#### 4. Railway Reserve Mines, Limited.

The development work on this property consisted of some trenching and shallow shaft sinking.

#### Right of Way Mining Company, Limited.

At the end of 1908 the total underground develop

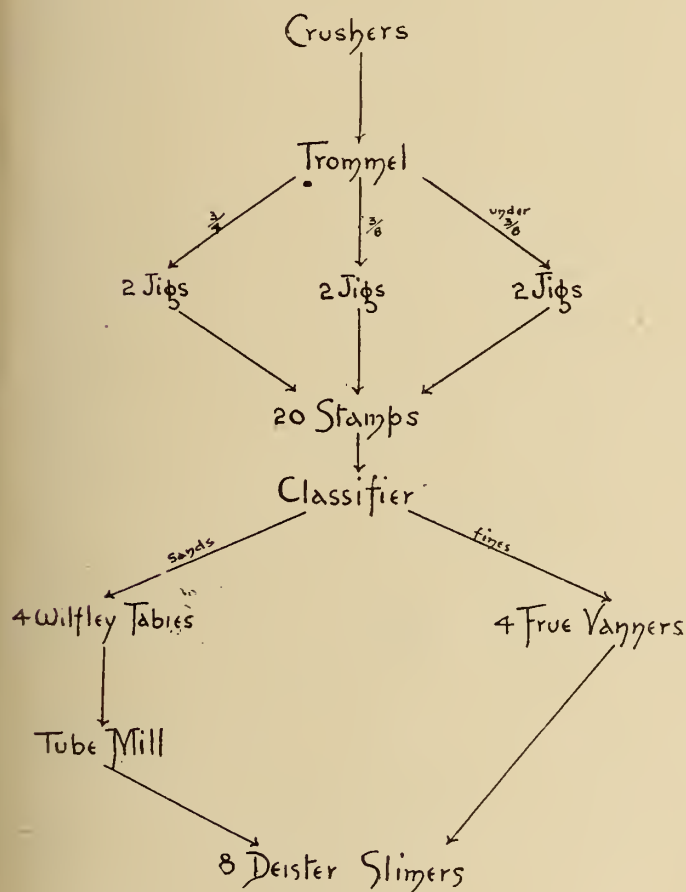

ment work of this company exclusive of stopes of the following:—

| —                          | Drifting | CrossCutting | Sinking |
|----------------------------|----------|--------------|---------|
| No. 1 .....                |          |              | 75      |
| No. 2 .....                | 1,094    | 1,890        | 563     |
| No. 3 .....                | 103      | 309.5        | 95      |
| Total to end of 1908 ..... | 1,197    | 2,199.5      | 733     |
| Total to end of 1907 ..... | 274      | 151          | 216     |
| Total for 1908 .....       | 923      | 2,048.5      | 517     |

#### 6. Wright Mining Company.

The work done on this property during 1908 consisted of the most part of surface trenching. In all

Flow Sheet, McKinley-Darragh Concentrator.  
(Under Construction.)

4,328 feet of trenches were dug, in many places being a depth of 10 to 12 feet. The only underground work was 56 feet of drifting.

#### 7. Jack Pot Silver Mining Company, Limited.

This property has been idle all year.

#### 8. Cobalt Station Grounds Mining Company.

The lease for this property was signed late in the year and the company only had time to do some surface prospecting.

#### 9. Ontario Development and Mining Co., Ltd.

This lot has been prospected by surface trenching and is now being tested by diamond drilling.

#### Progress During the Year 1908.

A rapid, but healthful advance marks the progress of the Cobalt District. The shipments in 1908 were greater than the combined shipments of the four previous years. A point that appeals particularly to the investing public is the fact that more than 50 per cent. of the value of the total output of the camp has been paid back to shareholders in dividends.

In the early work of the mines, while rich ore could be dug out on the surface, mining costs did not receive very serious attention. As development proceeds, however, production costs are being lowered, by such economies as the installation of large and more efficient machinery. Possibly the feature of the year in underground work has been the large introduction of air hammer drills for stope work.

Two power plants are being installed on the Montreal River and it is expected that before the end of 1909 power will be delivered in Cobalt by them, in one case in the form of compressed air, and in the other, electricity. The introduction of this power is likely to cut down the present cost by at least 50 per cent.

There are now about 3,500 men employed in the mines at Cobalt and in the immediate vicinity.

The horse power capacity of the camp is as follows:

| At the End of | Boiler H. P. |
|---------------|--------------|
| 1904 .....    | Zero         |
| 1905 .....    | 150          |
| 1906 .....    | 3,406        |
| 1907 .....    | 7,918        |
| 1908 .....    | 9,700        |

There are now 61 compressors which have a maximum capacity of 39,336 cubic feet of free air per minute.

Colored wrappers for dynamite cartridges have been suggested. This would facilitate the detection of unexploded cartridges lying in broken rock underground. Necessarily the wrappers should be of a color that is in sharp contrast to the ore and rock that is being worked. Another suggestion is that the wrappers should carry some striking design that would render detection easier.

Under the revised company law of the Transvaal the Attorney-General is provided with power to appoint inspectors to investigate the affairs of any company and to report on their conduct when he has been requisitioned to do so by members of a company having a share capital, such members holding not less than one-tenth of the issued shares between them, and also on the application of one-fifth of the number of persons on the register of a company not having a share capital.

Auriferous smaltite, impregnating quartzite, is being worked on a small scale north of Middleburg, on Kruis River, Transvaal.

According to the opinion of Mr. Lionel Phillips, retiring president of the Transvaal Chamber of Mines, it is the belief of many metallurgists that amalgamation plates can be dispensed with, and the whole of the free gold recovered by direct cyanide treatment. If experiments in this direction prove successful the opportunities for gold stealing by employees would be much reduced and smaller plants would serve the purpose.

# PETROLEUMS AND COALS.

## Compared in Their Nature, Mode of Occurrence and Origin.

By Eugene Coste, E.M., Toronto.

(Printed as an advance paper of the Canadian Mining Institute.)

(Continued from last issue.)

The total thickness of the formations more or less impregnated with the oil is about 25,600 feet. Although we have here three geological unconformities, meaning long lapses of time and erosion between the deposition of the different formations, yet the oil is in all of them through a thickness of over 25,000 feet of strata from and including crystalline rocks to the most recent gravels, but only along great faulted lines and zones of disturbances. There are three conclusions to be drawn from this, which are plain: 1st. The movements of the oil were vertical, not lateral. 2nd. Some of these movements at least were of recent date, namely, Post-Quaternary. 3rd. It cannot reasonably be supposed, as some geologists have, that this oil originated in any one of these formations (such as the Monterey, which is often cited by Arnold as the source of the oil) as this would entirely fail to explain the oil in the formations below the Monterey, and also the oil in unconformable formations above the Monterey. Oil formed from decomposition of organic remains in the Monterey, as supposed by Arnold, would either have remained in that formation, if the Monterey shales were impervious enough to prevent its escape into the atmosphere, or, if they were not, would have exhausted out into the atmosphere long before the Fernando and Quaternary strata were deposited unconformably over it. There is only one possible explanation, namely, solfataric volcanic emanations of hydrocarbons coming up from below the crystalline gneisses along the fault lines and in the zones of disturbances at repeated periods of dynamic movements of the Coast Range, and some of these movements must have been very recent to explain the oil in the gravels of the Quaternary. Even in the Monterey shales, as in all the so-called "bituminous shales" it is plain that the petroleum is a secondary product of impregnation subsequent to the forming of the shales, as evidenced by the facts that these shales are bituminous only along the zones of disturbances, and in local and irregular pools; in these it is not in any way spread over uniformly in one or more beds, but it is distributed in the shape of branching streaks, veins, patches, and in the joints and cracks; in fact, the portions impregnated with bitumen often look like a regular breccia, indicating plainly the injected nature of the bitumen.<sup>1</sup>

In one of my other papers<sup>2</sup> on this subject before this Institute I have emphasized by other examples this well-established geological fact with regard to the occurrences of petroleum, illustrated grandly by the California example just cited above, namely, that the petroleum deposits belong to no special horizon of the geological scale, but that they are found in any and all of them, including the crystalline rocks, and, as we have seen, also in volcanic emanations, in volcanic and igneous rocks, in metalliferous veins and in meteorites. When to this consideration we add the further one that

these petroleum deposits are found in great abundance in certain districts in the porous reservoir-rocks of thousands of feet of the geological scale, but only when these are aligned in narrow long belts along certain structural lines, while neighboring districts outside of these lines, but with the same geological sequence of formations are absolutely barren, we see that we must necessarily consider petroleum as secondary products of impregnation and replacement coming up along these structural channels from a source below the last formation in which it is found, namely, the crystalline rocks. It must also necessarily be inferred that the latest incoming or emanations of these secondary petroleum products through all these strata are younger than the youngest impregnated formation.

The solid petroleum is also found in zones of great fracturing and of profound disturbance in parallel vertical veins following the general direction of the orogenic uplifts of their particular district and cutting all the strata and in every way similar to mineral veins. This is well proven in California, Utah, Indian Territory, Galicia and other places, instances of which will be found in one of my other papers<sup>1</sup> on this subject. Arnold<sup>3</sup> and Ellis<sup>3</sup> have both shown instances from California and from the Barbadoes Islands, respectively, in which the solid petroleum was replaced in depth in the same vein by liquid petroleum.

In some of the more recently formed oil and gas deposits, as in Texas and Louisiana, where the oil and associated salt waters are often hot yet, the petroleum occurs in vertical chimneys of salt, gypsum, sulphur, calcite, dolomite, and silica, replacing and uplifting Quaternary. Tertiary and Cretaceous clays and sands, and forming peculiar qua-qua-versal domes called salines, mounds or salt islands. The local uplifts in some of the salines of Louisiana and Texas are extraordinary, as much as one to two thousand feet in an elliptical area, but a mile or so across, and these salines, as Capt. Lucas pointed out long ago, are ranged along straight lines. Mr. G. D. Harris, in an article just published,<sup>1</sup> gives us an interesting map of the structural lines of dislocation of this region, and shows that they belong to two systems more or less at right angles one to the other, and parallel to the great Balcones fault for the northeast system, and to the Red River and Alabama Landing fault for the northwest system. He also shows that the salines are all located along these lines of weakness, and he claims at the intersection of two of these lines where a still weaker point was determined "admitting the upward passage of fluids or gas under pressure from below:" but Mr. Harris is still under a similar impression, as Mr. Robt. T. Hill was,<sup>2</sup>

namely, that these gaseous and liquid substances are carried to these salines by artesian waters entering the pervious layers of the Mesozoic, or Paleozoic, far up country and going down to greater and greater depths as the latitude of the Gulf border is approached to ascend under hydrostatic pressure at the above mentioned points of weakness. As I have pointed out twice before,<sup>3</sup> several years ago, the pressure to which the fluids under the salines are subjected is not hydrostatic and it is also impossible for meteoric waters to gather and carry down from sediments the diversified products of these salines, especially insoluble liquid hydrocarbons and such gases as natural gas and hydrogen sulphide. Permit me to recall here the explanation of the nature of these salines, which I gave before this Institute six years ago<sup>1</sup>: "But, on this continent, in the newly-discovered oil fields of Texas and Louisiana, we have many no less direct evidences of vulcanism, though they do not appear to have been understood in their true light. These are the salt islands and the mounds of the Coast Prairie, such as the famous 'Spindletop,' near Beaumont, which are clearly nothing else but 'suffionis,' or 'salses,' hardly extinct yet, grouped along fractured lines and marking in that region the dying out of vulcanicity, that is to say, the dying, distant echo of that tremendous volcanic energy which, a little further south, in Mexico, Central America, and in the islands and along the south coast of the Caribbean Sea, is to this day so powerfully active. When these occurrences of petroleum in the Texas-Louisiana salines are considered in the light of what is now being found a little further south along the Gulf-Coast plain in the new oil fields of Mexico, where, as noticed above, the oil is found around many volcanic necks, it can be seen that the view which I took six years ago that these salines were regular solfataric volcanic vents, was the right one. In the Mexican oil fields the volcanic action has been a little more intense, and instead of only the hot gases, vapors and waters piercing up more or less through the horizontal strata to form the salines, as in Texas and Louisiana, we see the volcanic lava cones themselves piercing up boldly through the plains. There is, no doubt, that these lava cores in Mexico, surrounded with petroleum and other solfataric emanations, are one and the same volcanic phenomenon as the vertical chimney of salt, hot water and hot petroleum of the Texas-Louisiana salines.

**Origin.**—The opposite chemical nature of the members of the two series of natural carbon compounds, namely, oxidized complex carbon compounds for the coals and a mixture of reducing hydrocarbons for the petroleum, gives us the first hint of the surface or external origin of the coals, and of the internal origin of the petroleum. Beneath the earth's surface, as is well known, there is a deficit of oxygen, and hence we find none in the natural hydrocarbons from the interior, except in the solid varieties, which are the oxygenated and sulphureted residue of the other petroleum in places where they came near enough the surface. The coals on the contrary obtained their oxygen from the atmosphere at first in their original state of vegetation, and have retained part of it during the carbonizing process to which they have been subjected.

**Coal Series.**—The origin of the members of the coal series from the natural decomposition of vegetable matter, either in place or drifted, is abundantly proven,

and is now generally acknowledged and admitted among geologists.

**Petroleum Series.**—It is, however, very different in the case of the petroleum, the origin of which is still admitted by many, as a matter of fact requiring no demonstration, to be due to some unseen and unexplained decomposition of organic matter. Other geologists have discussed the subject at length, and have tried to prove the organic origin of the petroleum, but not one has ever been able to point out to a single case where a petroleum production process coeval with the kingdoms of life could be witnessed in Nature to-day. Some other geologists are discouraged and proclaim the origin of petroleum as a profound mystery not yet solved by science.

As I have long contended, I, for one, cannot understand how it is that the solfataric volcanic origin of the petroleum should be considered as any more doubtful and less proven than is the organic origin of the coals. It seems to me that the geological facts proving the one are just as clearly established scientifically to-day as are the facts proving the other. They are simple facts, the A B C, so to say, of geology, and yet strange to say, they are every day ignored and set aside.

There can be only two kinds of organic matter in nature to which the derivation of petroleum might be attributed, namely:—

First—The soft tissues of animals.

Second—Vegetation.

1st.—But the soft tissues of animals always decompose, decay completely and disappear entirely before their entombment in the sedimentary strata can possibly take place. It leaves us, therefore, only the vegetation to deal with in the consideration of this problem. That the soft tissues of dead animals entirely disappear before the entombment of their hard part, even in the comparatively rare cases where the entombment of the latter takes place, is one of the best known and best proven facts in geology—water, carbon dioxide and ammoniacal salts, are the chief products of the decomposition,<sup>1</sup> no petroleum is formed. If it had been otherwise we would not find, as we do, even in late Quaternary deposits, many beds composed entirely of ostras, corals, marls and shells of all kinds, such, for instance, as the "coquina" beds of Florida, absolutely devoid of some carbon compound to represent the supposed entombed soft tissues of the animals, while in the fossils, shells and other hard parts of the animal life, which we have collected in great abundance in our paleontological museums, from strata of every geological age, we would surely often see at least a modicum of some carbon-compound. But we may examine millions of these fossils and see nothing of the kind, even when these fossils have been collected in impervious shales from which the decomposed products of the soft tissues of the animals, if they had been entombed and had decomposed there, could not possibly have escaped. In very rare cases we do find portions of strata with shells or other fossils filled up with liquid petroleum, but in these cases we also find the seams, joints and other open or porous parts of these strata impregnated with the same fluid, showing plainly that it is a secondary product of infiltration and replacement. Many other substances have thus filtered through the strata and petrified or mineralized the

<sup>3</sup>Jour. Can. Min. Inst., Vol. VI, p. 93, and Trans. Am. Inst. Min. Eng., Vol. XXXV, pp. 292, 293.

<sup>1</sup>Jour. Can. Min. Inst., Vol. VI, p. 89.

<sup>1</sup>Bulletin U.S. Geol. Surv., No. 330, p. 116.

<sup>2</sup>Bulletin, U.S. Geol. Surv., No. 330, p. 635.

fossils, such as calcite, silica, pyrites and a great many others, including such metals as copper and mercury. In all such cases there can be no implication of a community of origin between the infiltrated products and the organism. Yet many geologists often quote some of these rare occurrences of petroleum in hard parts of organisms, and use them as evidence bearing in favor of the derivation of it from these organisms, whether fish, molluse, or other organisms. For instance, in a recent memoir on the natural hydrocarbons by Frank Wigglesworth Clarke,<sup>1</sup> I find the following: "Dicaulfaït observed that the copper shales of Mansfield are strongly impregnated with bitumen, and also rich in fossil fish. The petroleum of Galicia is always associated with menilitic schists, in which fish remains are peculiarly abundant. . . . G. A. Bertels, on the other hand, attributes the Caucasian petroleum to the decomposition of molluscs. In the Kuban district, the oil, accompanied by salt water, exudes directly from beds of molluscan remains, which occur in enormous quantities." I wish to point out in answer: that in the great majority of cases even traces of fossils of any kind are impossible to find in the prolific oil and gas sands of the United States, and of the other parts of the world at large, and, therefore, that one is arguing the rule from the exception when he relies on such rare cases, as cited above, for his proofs of the organic origin of the petroleum; also in the copper shales of Mansfield, there is as much reason to attribute an organic origin to the copper as to the petroleum; also that in Galicia the petroleum is found in much greater quantities than it is in the menilitic schists, in sands without any fossil fish, and that it is found also in very large quantities, as ozokerite, in parallel, and branching veins cutting lower strata than the menilitic schists; and, finally, that the salt water which exudes with the oil from the mollusks in the Kuban district must also have its origin in the decomposition of the mollusks, according to the reasoning used.

There are a few instances cited in geology of partially decomposed and preserved remains of animal bodies having been found, but these are most exceptional cases, such as a few remains preserved in the antiseptic waters of the peat bogs, or a few frozen remains of Elephas. These exceptions, of course, only confirm the rule, which is, that when there is anything left of animal life in the strata it is the shells or bones, or their moulds or casts, but there is no trace of the flesh or soft tissues to be found, as none of it was entombed.

All that has been written, therefore, about petroleum being derived by distillation or otherwise from the soft remains of animal organisms, whether macroscopic or microscopic, entombed in the strata, cannot possibly have taken place in the natural geological processes, since no such remains were ever entombed in the strata. C. Engler, C. M. Warren, F. H. Storer, S. P. Sadtler and others<sup>1</sup> have experimented and produced hydrocarbons by destructive distillation of organic animal matter, and these syntheses are often quoted by some geologists as very strong proofs in explaining the origin of the natural hydrocarbons in a similar way, but as has been shown above it is impossible to suppose that there could be any similar normal process in nature, since not only the soft parts of the animal organisms were never entombed in the strata, but the sediments in the oil fields were also

never subjected to the high temperatures required for the destructive distillation in such experiments, namely, between 300° and 400°.

2nd.—Now as to the vegetation: Is it not also absolutely and most abundantly proven that vegetation decomposes naturally into the coal series of carbon-compounds, and are not all the members of this coal series found in the sedimentary strata? Nothing more can be asked from vegetation. Are not all the stages, the beginning, the middle and the end of its gradual carbonizing process into peat, lignite, soft coal, semi-anthracite and anthracite right there before us ever since the very beginning of vegetation in Silurian or Cambrian times? Are we to disbelieve what we see to have taken place by the billions of tons during all ages since these most ancient periods, namely, that vegetation carbonized into the coals, and are we to imagine instead that some other unobserved, unseen and mysterious transformation of vegetation into something else, namely, petroleum, took place? This would be to lay aside an abundance of proven facts in order to adopt a mere supposition. The normal process of decomposition of vegetation into coals in nature is in active operation in the world to-day as it has always been, and it is the only one that we can see. It is also the only one of which we have any record in the long history of the geological ages.

As to the other argument that by destructive distillation the petroleum can be obtained from the coals, that would be all very well if nature had distilled the sedimentary strata and the coals or other vegetation in it, but, as a matter of absolute fact, it has not; therefore this line of argument also falls to the ground at once and can be dismissed. If the sedimentary strata had been distilled and petroleum thus produced, there would be no coals anywhere on the globe; we would have nothing but coke beds.

The beliefs in the organic origin of the petroleum leads also to chaos in the understanding of other geological facts and physical laws brought out clearly in the study of many petroleum occurrences or deposits, and no wonder that some geologists who are inclined to believe in this organic origin exclaim, therefore, that the genesis of petroleum is a profound mystery not yet solved by science. For instance:—

1.—It cannot possibly explain the large petroleum fields below the Carboniferous.

2nd.—Neither can it explain the petroleum in the volcanic emanations of to-day.

3rd.—Nor in the volcanic or igneous rocks in all parts of the world.

4th.—Nor in crystalline rocks; in California and New Brunswick, for instance.

5th.—Nor in meteorites.

6th.—Nor in metalliferous veins.

7th.—It is also at a loss to explain why the petroleum fields in every district are found grouped along certain lines, and why the petroleum is found there in many horizons, while outside of the lines in just the same strata, and over much larger areas, all the horizons are barren.

8th.—It cannot explain either how the petroleum can possibly travel out of their supposed organic-remain source in some impervious clay or shale to accumulate in a few porous receptacles far distant laterally and some times hundreds and thousands of feet above, or even below as some assert, and this all through most impervious rocks and without any impelling force behind, or any cracks, joints or fissures to follow since the decomposed products of the organisms must naturally

<sup>1</sup>Bulletin U.S. Geol. Surv., No. 330, pp. 629, 630.

<sup>1</sup>Trans. Am. Inst. Min. Eng., Vol. XXXV, pp. 290, 294.

be supposed to come from the whole mass of the strata through which the organisms were and there could not be fissures, cracks and joints to all parts of the strata.

9th.—It cannot possibly explain why the petroleum, although found to-day in their reservoir rock under strong pressures, cannot by means of that pressure, return and disperse back to their original sources; they should be able to return the way they came, nothing is to prevent them, and there is plenty of pressure for the return voyage if one admits the first voyage from the organic source.

10th.—It cannot possibly explain how the petroleum from the organic remains in the Monterey formation, for instance, in California, got out into the unconformable series above, such as the Fernando formation and the Quaternary, and why these petroleum did not all get out into the air during the long lapses of time marked by the unconformities, and how they were able to get into the lower Eocene and the still lower crystalline rocks, thus working their way against the pressure of their own natural gas, which always increases with the depth.

11th.—It cannot possibly explain again, if the petroleum can travel so freely through the strata as to be able to accumulate under an anticline from organic remains deposited far and wide laterally (at least a mile or two or much more in order to allow for the quantities obtained in many fields), why they did not escape out into the free air only a few hundred, or a few thousand feet away at most; the shales above the sands are not any more impervious than the shales below the sands, which, on that theory, are supposed to be the source of the petroleum, and if they can travel freely through the shales, which are the most impervious rocks of the sedimentary series, I repeat, what is to prevent them from getting out into the atmosphere?

12th.—It cannot account for the continual absence of petroleum in the hard parts of organisms preserved in the sedimentary strata.

13th.—It cannot explain the evident non-connection of petroleum deposits with coal beds.

14th.—It cannot account for the continual association of petroleum with strong salt and sulphur waters. The origin of the petroleum, therefore, is not organic; that it is volcanic is absolutely proven by:

1st.—The fact that volcanic emanations of hydrocarbons are the only natural geological process of petroleum production of to-day, abundantly verified and witnessed in actual operation in volcanic eruptions and phenomena all over the world.

2nd.—By the presence of petroleum in volcanic rocks, igneous rocks, metalliferous veins and meteorites.

3rd.—By the rock pressure of the natural gas in the petroleum deposits. This pressure always increases with depth in each field; it has been well proven that it is not an artesian water pressure from above, and it cannot be explained in any other way than as a remnant or spark of the volcanic energy forcing the petroleum through the crystalline rocks and all the sedimentary strata from below.

4th.—By the products associated with the petroleum in their reservoirs, principally salt, sulphur, hydrogen sulphide, gypsum, calcite, dolomite and silica, which are also the products associated with hydrocarbons in the volcanic emanations of to-day. This association is the unmistakable solfataric volcanic seal which I pointed out before.<sup>1</sup>

5th.—By the hot oils, gases and waters in some of the more recently formed petroleum fields.

6th.—By the fact that the petroleum deposits are located along the faulted and fissured zones of the crust of the earth, parallel to the great tectonic orogenic and volcanic dislocations and in "petroliferous provinces" analogous to the metallogenetic provinces of De Launay, Lindgren, Spurr and other writers. These petroleum deposits could not be inseparably and intimately connected with the tectonic structure of each particular region unless their source was as deep-seated as the forces which have caused these profound dislocations of the crust. We have gradually come to this conclusion in geology in regard to ore deposits similarly connected with tectonic disturbances and hydrocarbon gases and vapors must be added to this class of solfataric metalliferous emanations and receive their proper place in geology as solfataric "petroliferous" emanations. These "petroliferous" emanations have played a most important part in the deposition of ore bodies.

7th.—By this fact that petroleum are never indigenous to the strata in which they are found, and are clearly secondary products impregnating porous rocks of all ages. In all fields there is always a lower horizon in which the petroleum is found, until finally the crystalline rocks are reached, and they are even found in these. This adventitious nature of the petroleum deposits is further illustrated by the deposits of solid petroleum which cut through all rocks in veins exactly similar to mineral veins.

8th.—By the fact that petroleum are found in such abundance in certain small localities, while neighboring localities are found entirely barren; this forces one to the conclusion that they must originate from the volcanic tank below which is the only one adequate to furnish these enormous quantities to narrow, long belts or to small isolated spots, such, for instance, as the one hundred acres of the Spindletop Mound, near Beaumont, Texas, which has already produced about 38 million barrels of oil; such as the one billion barrels produced from a small area in the famous oil field of the volcanic peninsula of Apoheron, near Bakou, Russia; and such as the millions of barrels produced in many other fields from very narrow long belts, while areas, many scores of times larger, next to the producing strips are barren. This cannot be held to be an accumulation in the producing fields from vast surrounding areas of sediments, as if this was supposed one could not explain why the petroleum did not escape to the surface instead of travelling so far laterally.

9th.—By the fact that the sedimentary strata of the oil fields are so highly impervious that the volcanic fracturing and fissuring and the volcanic force of the natural gas alone can explain how so many small porous receptacles at different horizons between these impervious strata, have been filled with petroleum, salt and sulphur waters, and how these small detached petroleum reservoirs are found to-day under a gas pressure which increases with depth in each district, but is, nevertheless, a stored energy which will dissipate gradually in the utilization of the oil field, the volcanic energy which brought it there at one time being now dead and inactive.

Before concluding, permit me to insist on the fact that the recognition of the solfataric volcanic origin of the petroleum not only removes every difficulty in the way of a full comprehension of all the chemical and geological facts established to-day with regard to the nature and mode of occurrence of these products, but it fully harmonizes also with the physical laws governing the circulation of gases and liquids through great

thicknesses of very impervious strata before being able to reach to and accumulate in a few small separated receptacles in the midst of these. The volcanic origin of the petroleum forms, therefore, a complete chain of evidence, with none of the links weak or missing. The very reverse is the case, as I have shown above, when one attempts to explain the origin of the petroleum by means of organic sources; in doing so, well known chemical and geological facts are set aside and ignored and physical laws are distorted and abused. The geologists who still hold these views should seriously reflect on this, and I am confident that if they do they will soon abandon and relegate to the past the old unsupported notion of the derivation of petroleum from organisms, and that they will come to the conclusion that this idea is now unworthy of the progress made by the geological science of to-day.

When one considers that there were produced in the United States alone last year 184 million barrels of oil and fifty-three million dollars worth of natural gas, he can fully appreciate the great economical importance which petroleum has attained. It is essential, therefore, even leaving aside the purely scientific aspect of the question, that the origin of these products should be understood in order to afford a basis or guide for the intelligent exploration of the many new fields yet undiscovered, and which are to supply the world with even vaster quantities of petroleum in the future. The correct understanding of the volcanic origin of the petroleum furnishes us at once, as a matter of fact, with the solution of this problem of how and where to look for new fields; we must follow, as I have pointed out before, the structural or tectonic lines of disturbances and fissuring or the fractured belts along which the solfataric hydrocarbon emanations come up from the interior. The outward manifestation of these tectonic disturbances may be a fissured anticline, as it often is, but the fissuring may also have occurred at any other part of the structural folding of the strata whether in the syncline, at a monocline, along a slope or terrace or any other part of any form of structure. The so-called anticlinal theory, as heretofore explained and understood, namely, as a favorable place of accumulation under an arch of the supposed products of decomposition or distillation of organisms, is abso-

lutely untenable and without any meaning. That such products cannot and do not travel through impervious strata is well demonstrated by the fire damp and choke damp of the coal mines which are always found to-day right in the beds of coal from which they originated. If hydrocarbon gases and fluids could travel through the shales below the producing sands which in this organic theory are supposed to be their source, these hydrocarbon fluids would also travel just as freely through the shales and other strata above the sands and, therefore, would have escaped out into the atmosphere long ago instead of stopping under the anticlines. There is absolutely no difference between the degree of perviousness of the strata above or below the sands, in fact very often a shale which is above a producing sand is also below another producing sand. All these strata are highly impervious, including even the "sands" which are porous only in occasional comparatively small spots. It has been impossible, therefore, for gases and fluids to travel through the strata except when they were fissured by profound dynamic disturbances, which permitted the tremendous volcanic pressure from below to exert itself, and even then the enormously pent up gases and vapors from the interior reached to or near the surface with great difficulty as exemplified by the great differences in pressures of the natural gas in different sands at various levels in a given field, by the fact that pressures of 500 to 600 lbs. to the square inch are often obtained quite near the surface at depths of only 800 to 1,000 feet, yet the gas did not escape; and, by the further fact that oil and gas fields are such small detached pools, never extending but short distances away from the dynamic disturbances which form their original channels. It is only as a part of this broader conception of the occurrence of the petroleum-fields along the profound structural disturbances that the so-called anticlinal theory has any merit. This conception alone explains why some fissured anticlines are "petroliferous" or petroleum-bearing in several of their sands at different horizons, while the great majority of anticlines are absolutely barren of hydrocarbons at all their horizons because they are not fissured folds in "petroliferous provinces."

## MINERAL DEPOSITS OF THE SERPENTINE BELT OF SOUTHERN QUEBEC.

By John A. Dresser, McGill University, Montreal.

From the Journal of the Canadian Mining Institute.

(Published by permission of the Director of the Geological Survey of Canada.)

### I. General.

For the past few years practically one-half of the mineral output of the Province of Quebec has been obtained from the area in the Eastern Townships known as the serpentine belt. This is a complex of igneous and metamorphic rocks consisting of peridotite, pyroxenite, diabase and granite, with serpentine and talc schists. It is rather because of the greater economic importance of the serpentine and the fact that it is a rock more easily recognized, than on account of its relative area; that the name serpentine is commonly applied to the group.

These rocks form part of a series which extends, with some interruptions, in a line parallel to the Atlantic coast from Georgia to Newfoundland. In the Province of Quebec they are almost continuous from the international boundary line near Lake Memphremagog to Thetford Mines. Beyond this to the north-eastward they appear frequently for a distance of eighty miles in the counties of Beauce, Dorchester, Bellechasse, Montmagny and L'Islet, and after an interval of some 120 miles they reappear with a large development in the Shickshock Mountains of Gaspé. They are best known in the counties of Megantic,

Wolfe, Richmond, Sherbrooke, Shefford and Brome.

The present output of asbestos comes from the counties of Megantic and Richmond; of chromic iron from Megantic and Wolfe. In each case the County of Megantic furnishes the principal production.

## II. Geology.

The geological relations of the serpentines and associated rocks are not yet very completely known. They are, however, an intrusive series, the latest of which cut sedimentary strata of middle Ordovician age. Some portions seem to be laccolites uncovered by denudation, while others are probably extrusive masses with plutonic rocks in the central portions which pass into diabase towards the sides and top, and have since been deeply eroded. The whole series has been much folded and deformed by regional metamorphism.

The peridotite and pyroxenite are parts of one original mass, which have been differentiated from

have been mentioned. Further field work is necessary to define the precise relations of these rocks. The diabase occupies much the greater portion of the entire belt, and also forms all the higher hills, such as Broughton, Adstock, Ham, Orford and Owls Head Mountains.

A peculiar hornblende granite cuts these rocks with numerous dykes and is otherwise intimately associated with them.

Mineral deposits of importance are found in this district in each of the above-mentioned rocks, except the last. Asbestos occurs in the serpentine; chromic iron in serpentine and peridotite; talc in the pyroxenite; and associated with the diabase there are copper, antimony and nickel.

## III. Asbestos.

Although asbestos was known in the Eastern Townships as early as 1847, it was not until thirty years later that it became commercially important. Work was

FIG. I.

each other. The serpentine in the Thetford-Black Lake and Danville districts has originated from the alteration of the peridotite. That of the East Broughton and related occurrence has apparently been derived from a and fifteen in width, underlying a great part of the very similar rock, but is in a much more advanced stage of alteration and doubtless is much older. Isolated outcrops of this older serpentine appear at various places in the counties of Wolfe, Megantic and Lotbinière, and are probably portions of a partially uncovered large mass, or batholith, at least fifty miles long dome-shaped hilly country between the Quebec Central and the Grand Trunk Railways in this district. This serpentine is probably of pre-Cambrian age.

The diabase forms a marginal or outer facies of the peridotites and pyroxenites in some parts of the district, but in others it cuts serpentine that is thought to belong to the later of the two classes of that rock that

begun in 1877 at Thetford, and almost at the same time at Black Lake and Danville, and has steadily advanced ever since. The mineral, which is the chrysotile variety of asbestos, fibrous serpentine, requires no description. It has the same chemical composition as the rock which contains it. It is valuable for the property of being incombustible, and that it is a most successful non-conductor of heat and electricity, and well resists most acids. It is used for an increasingly large number of purposes every year, such as stage curtains, fire screens, boiler covering, fireproof roofing and covering, insulating material, etc. The product has hitherto been manufactured in the United States and in Europe, but at present large works for the manufacture of asbestos are being installed in Canada.

1. Production.—Asbestos mining is now the most important mineral industry in the Province of Quebec. During the last thirty years, that is, since asbestos

mining began, the aggregate production has had a value of more than twenty million dollars, and at the present time the Province of Quebec produces between 85 and 90 per cent. of the world's supply. This entire amount, in value two and a half million dollars, is obtained from the counties of Megantic and Richmond, much the greater part coming from the former. The following returns of production indicate the growth of the industry. The production of low-grade material was greatly increased by the introduction of mechanical concentration in 1892-3-4, and the effect is well shown in the statistics which are taken from the returns of the Geological Survey of Canada:—

| Production.          | Value.    |
|----------------------|-----------|
| 1878— 50 tons.....\$ | —         |
| 1879— 300 “ .....    | 19,500    |
| 1880— 380 “ .....    | 24,700    |
| 1881— 540 “ .....    | 35,100    |
| 1882— 810 “ .....    | 52,650    |
| 1883— 955 “ .....    | 68,750    |
| 1884— 1,141 “ .....  | 75,097    |
| 1885— 2,440 “ .....  | 142,441   |
| 1886— 3,458 “ .....  | 206,251   |
| 1887— 4,619 “ .....  | 226,976   |
| 1888— 4,404 “ .....  | 255,007   |
| 1889— 6,113 “ .....  | 426,554   |
| 1890— 9,860 “ .....  | 1,260,240 |
| 1891— 9,279 “ .....  | 999,878   |
| 1892— 6,082 “ .....  | 390,462   |
| 1893— 6,331 “ .....  | 310,156   |
| 1894— 7,630 “ .....  | 420,825   |
| 1895— 8,756 “ .....  | 368,178   |
| 1896— 10,892 “ ..... | 423,066   |
| 1897— 13,202 “ ..... | 399,528   |
| 1898— 16,124 “ ..... | 475,131   |
| 1899— 17,790 “ ..... | 468,635   |
| 1900— 21,621 “ ..... | 729,886   |

| 1902— 30,219 “ ..... | 1,126,688 |
| 1903— 31,129 “ ..... | 915,888   |
| 1904— 35,611 “ ..... | 1,213,502 |
| 1905— 50,669 “ ..... | 1,486,359 |
| 1906— 60,761 “ ..... | 2,036,428 |
| 1907— 62,241 “ ..... | 2,484,768 |
| 1908— 65,534 “ ..... | 2,547,507 |

2. Distribution of the Deposits.—In the Thetford and Danville areas workable asbestos has as yet been found only in the northwestern parts. The areas of serpentine in these two localities are not connected at the surface, but being lithologically similar and both intrusive, it is probable that they are portions of one general mass, and so are connected at no great depth beneath the surface. The rocks of each of these localities ranges from peridotite, rich in olivine, to pyroxenite, in which little olivine occurs. There is also much diabase in both areas. The peridotite is largely altered to serpentine, but it is in the latter only that asbestos occurs. In the cooling of the peridotite-pyroxenite magma there appears to have been a segregation of olivine towards the northwestern edge of the mass, and of pyroxene towards the southeast side.

The greater part of the entire rock mass is most suitably called serpentine, but much of it carries from 10 to 20 per cent. of pyroxene, generally bronzite, and forms a hard rock, which the miners call “dry” or “bastard” serpentine, or “hornblende rock.” The “heads” or masses of hard rock often met with in the

asbestos mines are of the same character. On the other hand the more pure serpentine which produces asbestos is distinguished by a softness of feel and a more uniformly light colour. The original rock in this case was richer in olivine and poorer in pyroxene, and probably contained less chromite, which is disseminated more or less freely through all of this rock mass.

The distribution of the asbestos-bearing portions of the serpentine, therefore, seems to depend on differentiation in the primary rock, by which a relatively small proportion of it became rich enough in olivine to form a comparatively pure serpentine. While the productive portions are small in proportion to the entire body of serpentine, they nevertheless form asbestos deposits that are practically inexhaustible.

3. Character of the Veins.—The asbestos occurs in gash veins, which rarely reach three inches in width or exceed two hundred feet in length. The great majority are less than three-quarters of an inch wide, and are only a few feet in length. The fibres of asbestos run transversely to the veins, and hence perpendicularly to the side walls. Thin films of iron ore, sometimes chromite, but more frequently magnetite, often form partings in the vein, or coat the ends of the fibres.

4. Origin of the Veins.—The identity in composition of asbestos and serpentine and the evident vein structure show that the material of the veins has come from the side walls. But while all investigators have practically agreed upon the source of the material of the veins, there has been less unanimity in the opinions that have been expressed as to how the veins were formed, and more especially as to the origin of the fissures.

The serpentine is generally much fractured and slickensided along the fracture planes. The late T. Sterry Hunt attributed this in a great measure to the increase of volume which would accompany the change of the anhydrous silicate, olivine, to the hydrous silicate, serpentine. The slickensided fracture planes, however, are less frequently walls of asbestos veins, and consequently this observation does not apply to the origin of these veins.

J. H. Pratt (U.S.G.S., 1904) says that “the original rock in cooling would solidify first along its contact with any included masses of the country rock, that had been broken off during the intrusion of the molten magma. The outer portions of the molten rock would thus cool much more suddenly than the interior portions, and there would be a tendency for them to develop cracks and parting planes. In the alteration of these primary rocks to serpentine, through the agency of aqueous solutions, vapours, etc., there would be perhaps, to some extent at least, a widening of these cracks, but in the end they would be filled with serpentine deposited from aqueous solutions from their walls, and the resulting fibrous structure of the serpentine filling these seams represents the nearest approach to a true crystallization that the mineral serpentine assumes, except when it is found as pseudomorph after another mineral.”

G. P. Merrill, Smithsonian Institution, Washington, D.C., (Mining World, 1905), attributes the fracturing to shrinkage due to the partial dehydration of the serpentine, and also to loss of silica, as has been suggested by J. F. Kemp (N. Y. Acad. Sci., 1901), comparing the veins to the shrinkage cracks in serpentine nodules. He considers the asbestos fibres to have grown from one or both sides of the vein, according as it is an undivided or a divided vein.

R. W. Ells (Bulletin on Asbestos, 1903, Geological Survey of Canada) says of asbestos veins: "In whatever way the fissures were caused, and it is very probable that they have been formed by the great processes of metamorphism to which the rocks were exposed in the change from dioritic matter to serpentine, the vein asbestos appears more naturally to have been produced

were probably formed by shrinkage of the mass, and perhaps in part the crushing action of the same pressure which lengthened and flattened the serpentine areas, and at the same time made the associated rocks schistose. The asbestos appears to the writer to have been deposited in the cracks under great pressure from superheated waters which, penetrating the rock, ab-

FIG. II.—Diagram showing asbestos and serpentine in peridotite. The largest vein is two inches wide.

by a process of segregation of serpentinous matter from the sides of the fissures very much as ordinary quartz in mineral veins is known to have been produced."

F. Cirkel ("Asbestos, its Occurrence, Exploitation and Uses," Department of Mines, Ottawa, 1905) agrees in part with Messrs. Merrill and Kemp, but considers

sorbed the material of the serpentine until the solution became a saturated one. With cooling, the mineral would be deposited in the cracks. . . . In the Thetford and Black Lake areas, masses and dykes of granite have been intruded into the serpentine, and these probably account for the necessary pressure and heated waters to form the asbestos there."

FIG. III.—Showing veins of asbestos within band of serpentine on weathered surface of peridotite.

a part of the fracturing to have been caused by the intrusion of granite dykes, which are numerous in the district. He also considers the veins to have been successively filled from the side walls.

A. P. Low (Geological Survey of Canada, 1906, The Chibougamou Mining Region) says: "The cracks

An important feature of asbestos veins that seems to have been generally overlooked is that the wall rock adjacent to the vein is always completely reduced to serpentine, while the general mass of the country rock is usually not so far altered. In all the deposits, except those of the East Broughton type, the asbestos-bearing

rock is only partially altered to serpentine, except along the asbestos veins, and here the alteration appears to be invariably complete. A band of pure serpentine extends on each side of the asbestos vein to a width generally about three times that of the vein. Measurements were taken on forty-nine veins in the Bell and Johnson mines, and the average ratio width of the asbestos vein to the total band of asbestos and bordering serpentine was 1:6.6, seventeen of the forty-nine measurements practically coinciding with this average. The serpentine border is not easily noticeable in fresh rock, but is very conspicuous on the faces of workings which have had fifteen or twenty years' exposure to the weather, and can often be well seen on unworked surfaces (Figs. 2 and 3).

The veins occur in the joint planes of the original rock, in fractures produced by regional metamorphism, and often in the crevices formed when shells are being

mon in the veins, would thus be the beginning of the vein, and chrysotile crystals by growing outward on either side would thus have formed the wider veins as the serpentinization of the wall rock advanced. The asbestos can only have been formed after the serpentinization of adjacent parts of the rock.

Pratt (op. cit.) observed that "It is probable that this chrysotile asbestos may have been formed some time before the complete alteration of the primary rock into serpentine. This is emphasized by the fact that in the southern part of the United States, where these magnesian rocks have been but partly altered to serpentine, seams of chrysotile asbestos are occasionally found almost entirely enclosed by a peridotite rock which is altered but little to serpentine." In the case shown in Fig. 2, a microscopic examination of the rock from the two portions marked No. 2048 and No. 2049 showed the latter to be wholly serpentine, the former

FIG. 1V.—Photomicrograph of specimen 2048. Rock about 90 per cent. olivine. Olivine grains surrounded by narrow rims of serpentine, a vein of asbestos, and a crystal of pyroxene.

cast off rectangular blocks as in weathering. All three types of fissures are indicated by the veins in Fig. 2, which is a drawing of a wall of a pit near the Standard mine. At the junction of two veins, one, usually the wider, sometimes cuts the other distinctly, but more frequently they coalesce with a short line of division between them, masked by a film of iron.

While the veins run in all directions through the rock, the larger veins are usually those along joint planes. Of these the horizontal series, which are sometimes over two inches wide and extend for 100 to 200 feet, could never have been open fissures, nor is it conceivable that small areas of rich ground occasionally found where there may be 12 or 14 per cent. of asbestos could ever have had as many open fissures as they now have filled veins. It therefore seems most probable that a process of replacement of the wall rock has gone on contemporaneously with the deposition of the asbestos. The film of iron ore, or the parting so com-

a fairly fresh peridotite. Figs. 4 and 5 show microphotographs of these sections.

At East Broughton and other localities on the older serpentine, the entire rock is of the character of the vein borders at Thetford.

The entire rock being serpentinized, the proportion of veins is large. Asbestos seems to have reached its maximum development which from the measurements made at Thetford would represent nearly one-seventh or upwards of 15 per cent. of the serpentine. But this rock has passed its maximum stage of productive value for an alteration of the larger veins has begun, by which the fibres of asbestos are partially replaced by calcite. Their flexibility and tensile strength being gone, they are no longer products of value. The best asbestos of this locality seems to be in the smaller veins. The rock is exceedingly soft, and the proportion of vein matter is so great that practically all of the rock mined goes to the mill. The fact that the asbestos

is of better quality in the narrow veins than in the larger ones appears to corroborate the view that the asbestos veins are gradually formed. Beginning along the joint planes, they extend to all parts of the rock as fracturing from any cause opens it to the action of metamorphosing agencies, principally water. These have reduced it first to serpentine; second, to asbestos, and lastly, forming a sort of ophicalcite.

Mr. W. S. Johnson states that veins of asbestos partially replaced by calcite are occasionally found at Coleraine. In that case, the Thetford area may be regarded as having reached the maximum productive value for asbestos.

According to the measurements mentioned above, this should be nearly 15 per cent. While this is in excess of the actual production of the rock as a whole, small very productive parts probably reach 12 to 14 per cent. occasionally, which, allowing for loss in recovery, accords fairly well with the results of the limited

the serpentine. It forms isolated masses of even grain, is separated from the serpentine by intermediate rock matter and seems, from such evidence as is available, to be an extreme differentiation product complementary to the very basic peridotite. This view, which is as yet only tentatively advanced owing to lack of sufficient field study, seems also to be corroborated by the fact that the granite is less frequently found in parts of the rock rich in pyroxene than in those having much olivine.

(To be continued.)

#### OUR SUBSTITUTE FOR TIMBER.

Abstracted from article by Prof. M. B. Baker, in Queen's Quarterly.

Notwithstanding the fact that our supplies of building timber are rapidly disappearing, little provision is

FIG. V.—Photomicrograph of specimen 2049. Serpentine and a few grains of chromite.

number of measurements on which this estimate of possible proportion of asbestos to serpentine is based.

5. The Granite.—The presence of granite in dykes or other forms has been considered by many to be favourable, if not necessary, to the occurrence of rich asbestos ground. Yet in the older serpentine at East Broughton the recent development of numerous areas now rich and formerly much richer, has not, so far as the writer is aware, disclosed any granite in that district. It would not, therefore, appear to be necessary to the existence of asbestos.

Where the granite is intrusive, as in parts of the Thetford and Danville districts, the effect in fracturing the serpentine is highly probable, and the influence of heated waters accompanying the intrusion, as suggested by Dr. Low, is likely to have hastened the process of serpentinization and the consequent formation of asbestos. But much of the granite appears to be nearly, if not quite, contemporaneous with the parent rock of

being made to supply a substitute. However, the demand for timber is not likely to increase so rapidly in the future as people think. Timber was formerly the chief structural material of all buildings, but is rapidly being replaced by steel, concrete, and clay products.

Stone and concrete are almost always used in the foundations of large buildings. The superstructures are either steel bridgework or reinforced concrete. The uprights, girders, joists, etc., are built to carry all the load, and some light fireproof material is used to fill in the spaces between the more substantial structures. In Canada the material used is usually clay, of which we have an endless supply.

The manufacture of clay products is probably the oldest industry on earth, but new developments are constantly being made nevertheless. One of the most recent of these is the manufacture of "clay-lumber," or "terra-cotta lumber," as it is often called. It is so-

made that nails, screws, bolts, etc., can be driven into it with ease, and it may therefore be put to many of the uses to which timber is now suited.

When clay is heated to a temperature of about 1,800 degrees it begins to fuse, and the particles weld or knit together, and the clinker when coiled assumes a hard rocklike consistency. In the manufacture of clay lumber the raw clay is mixed with some combustible substance, usually sawdust, and sufficient water to make a stiff mud. This mixture is then put through an auger machine, which consists of a hollow steel barrel about the shape of a cannon, within which an auger is turning, thus constantly forcing the clay towards the muzzle of the machine. Dies of any desired shape are bolted onto the muzzle of the machine, and as the clay is forced out it must of necessity take the shape desired. The clay issues as a long column, which can be cut off into blocks of proper size by means of fine wires set on a frame. By changing the dies to suit the architect's plans, any shape of block may be made suitable for domes, arches, ceilings, etc. When the products are sufficiently dried they are placed in a kiln, and the sawdust or other combustible, mixed with the clay, will burn out, thus helping to distribute the heat, and at the same time producing a light, porous, and fire-proof block.

For walls and partitions this clay-lumber is made in the form of hollow blocks, which have many other advantages, besides being light in weight. The air space within the blocks keeps the building cooler in summer and warmer in winter, and also deadens the noise from surroundings. Owing to the porous character of the blocks, one can plaster and finish walls and ceilings without first lathing them; but if one wishes to finish with lumber of any particular kind he can nail into this clay-lumber almost as easily as into timber.

Another class of hollow blocks differs from the porous, in that they are made entirely of clay, with no addition of sawdust or other combustible material. They are in reality hollow rectangular tile, and being free from pores are stronger, and able to carry a much greater load. They are usually made 8 inches deep by 10 inches wide, and 12 to 16 inches long. They have two or three partitions inside to give greater strength, the material of the walls and partitions being an inch thick. These blocks have long been used for foundations of frame houses, barns, stables, and frame structures in general. They build up a wall very quickly, and, being hollow, they offer a warm, dry, cheap form of masonry for foundations of frame buildings.

Enquiry among men from all Canada who would be most likely to know, failed to bring forth a single case where lightning has struck a building placed on these blocks.

Porcelain, which is used largely as an insulator, is simply a burned clay, as are the blocks described above. It is therefore possible that those hollow porcelain-like blocks do actually insulate a building from the earth, and thus leave it out of a possible electric circuit.

### WASHING BLAST FURNACE GAS.

On this subject the "Allgemeine Ingenieur Zeitung" has an interesting article, which, in view of the rapid introduction of large gas motors in connection with blast furnaces in America as well as in other countries, should prove of interest to a large circle of readers.

The purification of the gas before it enters the

working cylinder of the motor is one of the main conditions necessary to secure reliable working of the plant. Before the gas motor was brought into use blast furnace engineers paid little attention to washing the gas, as this seemed hardly necessary for its employment in the Cowper regenerators. A few dust catchers in the pipes seemed enough to do away with the necessity of frequent cleaning out of the regenerators. This is, however, not the case with motors where those parts that are subject to the action of the gas are exposed to considerable friction when at work at high temperatures. The great heat of explosion bakes the solid impurities on to the cylinder walls, etc.; the dust particles form with the lubricating oil a specially adhesive gummy mass, which is driven out with the combustion gases. But at the edges of the exhaust orifice there remains a great part of these substances, because it cannot keep up with the velocity of the gases. If we consider a gas motor of 500 h.p. using hourly 3.5 cubic metres, or say 123 cubic feet of gas, per horsepower, we have every hour 1,750 cubic metres, or say 61,250 cubic feet of gas passing through the machine; and if there is only one gram of dust per cubic metre, or say roughly 0.3 grains per cubic foot, we have every hour 1.75 kg., or 3.85 lbs. That at least one-fifth to one-fourth of this remains attached to the exhaust opening, can be seen by anyone who has to do with a motor working with unpurified gas, as every few hours he must remove this deposit. This latter closes the exhaust opening, and as a part thereof is sucked back by the piston into the cylinder, it injures the working surfaces. This shows that purification must be carried out to a degree which will leave less than one gram per cubic metre, or 0.3 grains per cubic foot; and in delivering motors the makers generally specify that the gas shall not contain more than 0.05 to 0.07 gram per cubic meter, or 0.015 to 0.021 grains per cubic foot.

The gas washers most in use can be classified in two groups. In the older of the two the gas is driven through a series of filtering vessels, containing for convenience a number of drawers, which may be taken out for emptying. The filtering material is usually coke, sawdust, or the like. The second class is of more recent construction, and well known under the name of rotary gas washers. The gas is passed through the jacket of a centrifugal apparatus, while the inner wall is covered with trickling water. The gas flows in the opposite direction to the latter, so that there is friction between the finely divided water and the whirling gas current.

The high degree of purification which can be carried out to a few milligrams of dust per cubic metre is due to the fact that the water forms a nebula which surrounds the finest grains of dust, and by increasing their weight, makes them more subject to the centrifugal action. Water and dust are thrown out together by the machine. To attain the highest possible degree of perfection by this method it is advisable to set the rotary gas-washer near the blast furnace, and even to insulate the pipe between the furnace and the washer, so that the gas shall not lose any of the heat necessary to evaporate the water.

The essential difference between the first-named class of purifiers and the rotary washers is that the first cost nothing, except for the material to fill the drawers and the labor to remove them, whereas the latter, exerting a suction action, call for considerable power to drive them. Further, they demand more

labor and are more expensive to keep up, so that very often it is found that the dry process is much cheaper than the washing. Outside of this, they need no provision for the removal of the water.

In the case of coke furnaces, and in general everywhere where the gas contains considerable water, only the dry process can be employed, as these very thoroughly remove this material from the gas. Of course, where the gas is not rich in tar, this makes no difference.

To get the advantage of both methods of purification, it is recommended so to construct the dry purifiers that they shall produce the same effect as that carried out in the rotary washers. This is done by building above the cylindrical purifiers a hopper-shaped reservoir, in which the gas current is led, and after

the latter has attained at the lower end a certain velocity, steam is driven through it. In the lower end of the hopper or funnel there is a spiral such as is found in grain cleaners and in some steam-drying apparatus. In this spiral the steam will have the same result as in the rotary washers.

It is to be remarked in this connection that to overcome the resistance in the spiral, neither increase of blast pressure nor the use of an exhaust fan is necessary. The steam, which is mixed with the gas at the end of the funnel, acts by its expansion like an injector—or rather ejector—and gives the gas the necessary increased velocity to enable it to flow through the spiral. After leaving the latter, the steam, mixed with the dust, is led into a condenser cooled by air, whence it is discharged as water.

R. G.

## BOOK REVIEWS.

**Principles of Mining: Valuation, Organization, and Administration; Copper, Gold, Lead, Silver, Tin, and Zinc.** By Herbert C. Hoover. 199 pages. Illustrated. Price \$2.50 net. Hill Publishing Company, 505 Pearl Street, New York.

Few individual phases of mining have not been touched upon in the writings of modern technologists. Specific problems have been debated and settled and reopened. From power economy to slime treatment, every step in the winning and reduction of gold ore has served as a crystallizing point for numberless expositions. Only less expounded are the mining processes of copper, lead, silver, tin and zinc.

But underlying these commercial processes are certain principles common to all. The proper understanding of these is a pre-essential to intelligent mining engineering. Mr. Hoover's book is written with the object of defining and illustrating these principles.

Before expressing an opinion on Mr. Hoover's method of handling his wide subject, let us glance at the general anatomy of the book itself.

The twenty chapters that make up the volume may be grouped thus: Six are given to "Mine Valuation"; three to "Development of Mines"; one to "Stoping"; one to "Methods of Supporting Excavation"; three to "Mechanical Equipment"; one to "Ratio of Output to the Mine"; three to "Administration"; one to "The Amount of Risk in Mining Investments," and a concluding chapter to "The Character, Training and Obligations of the Mining Engineering Profession."

Strict logic might demand that the last chapter be given first place. Otherwise there is no fault to be found with Mr. Hoover's arrangement of subject.

The author excludes from his consideration alluvial deposits, iron, coal, and all other mines except those in which the ores of the metals mentioned in the title are won. This differentiation strikes us as being arbitrary. For instance, on page 1, the following principles are given as forming the basis of the value of a metal mine:

- (a) The profit that may be won from ore exposed.
- (b) The prospective profit to be derived from extension of the ore beyond exposures.
- (c) The effect of a higher or lower price of metal (except in gold mines).
- (d) The efficiency of the management during realization.

These principles need no modification to become applicable to all types of mines and only slight changes will adapt them to the exploitation of alluvial deposits. We regret, then, that Mr. Hoover has not made his book more complete by including the vitally important coal and iron branches of mining. This by the way.

Comment upon a few typical passages, chosen more or less at random from successive chapters, will serve to convey a rough impression of the character and style of "Principles of Mining."

On the the first pages some truths that will always stand iteration are emphasized. ". . . it is utterly impossible accurately to value any mine, owing to the many speculative factors involved. The best that can be done is to state that the value lies between certain limits, and that various stages above the minimum given represent various degrees of risk" This is true. But it is also true that the fact that a mining risk is different from ordinary commercial risks does not mean that the former is necessarily higher. Speculative factors abound in everything from religion to street cleaning. Life insurance is highly organized speculation. The artist speculates in human sensibilities; the novelist, in human sentimentality; the broker, in human frailty. Heretofore it has been the almost invariable custom of writers to refer to mining risks as carrying an essential and not an incidental speculative element. Books like Mr. Hoover's will be most effective in rectifying this error. Nevertheless, Mr. Hoover himself appears to have accepted the current idea.

Mine valuation is abundantly treated. On page 4 it is pointed out that the treatment on a considerable scale of sufficient test parcels of ore is the ideal method. But such a method consumes time, opens many channels for fraud and is often either prohibitively expensive or physically impossible. Sampling and assaying are therefore the usual and accepted methods for determining the value of standing ore.

After developing this idea, Mr. Hoover makes some most sensible remarks on sampling. "The whole theory of sampling is based on the distribution of metals through the ore body with more or less regularity, so that if small portions, that is samples, be taken from a sufficient number of points, their average will represent fairly closely the unit value of the ore. . . . How frequently samples must be taken, the manner of taking them, and the quantity that constitutes a fair sample, are matters that vary with each mine. So much de-

pend upon the proper performance of this task that it is in fact the most critical feature of mine examination. Ten samples properly taken are more valuable than five hundred slovenly ones. . . . Given a good sampling and a proper assay plan, the valuation of a mine is two-thirds accomplished. It should be an inflexible principle in examinations for purchase that every sample must be taken under the personal supervision of the examining engineer or his trusted assistants."

This is a lengthy quotation; we would like to quote as much more. From the above, however, the reader may observe the colour and tone of the chapter. The section on sampling includes many general hints that are the fruit of ripe and right experience. There follow, next, sections and chapters on calculations of averages and of quantities of ores, classification of ore in sight, extension in depth, depth of exhaustion, recoverable percentage, cost of production, redemption of capital and interest, valuation of mines with little or no ore in sight, valuations on second-hand data, general conduct of examinations, and reports. This concludes that part of the book assigned to the general topic, "Mine Valuation."

It is not seemly to do much more than express our warm approval of the crisp, capable and accurate treatment that the author gives this theme. One digression will, we hope, be pardoned. On page 56 there is a paragraph on mining engineers' reports that is temptingly quotable. It gives clear expression to views that should be more generally held and acted upon. It leaves no room for the mere "opinion" of the genuine engineer, nor for the resounding periods of the pretender. Here is part of it:

"Reports are to be read by the layman, and their first qualities should be simplicity of terms and de-

finiteness of conclusions. . . . The essential facts governing the value of a mine can be expressed on one sheet of paper. It is always desirable, however, that the groundwork data and the manner of their determination should be set out with such detail that any other engineer could come to the same conclusion if he accepted the facts as accurately determined. . . . The wise engineer will put before his clients the scale, the weights, and the conclusion arrived at. The shrewd investor will require to know these of his adviser."

Under "Development of Mines," such matters as entry to the mine, tunnels, location of shafts, speed of sinking, crosseuts, drilling, etc., etc., are given practical consideration. Tabulated working costs are given by way of illustration and numerous diagrams are inserted. "Stopping" has a chapter to itself, as also has "Methods of Supporting Excavation." "Mechanical Equipment" is very fully discussed. Administration, volume of output, the amount of risk in mining investments, are concluding subjects. The last chapter, "The Character, Training and Obligations of the Mining Engineering Profession," will be the text for editorial comment at a later date.

Already Mr. Hoover's new book has had a wide sale. This is not the least acceptable form of approval. The title, "Principles of Mining," is inviting. The book itself is not disappointing. It argues well for the author's literary perspective that he has been able to confine himself to a modest two-hundred-page volume. This means that he has skilfully avoided diffuseness, verbosity, and unprofitableness of that kind. Whether he has or has not been guilty of serious sins of omission we are not prepared to say. He has given the reading public a readable book that should have a large influence for good with engineers and investors alike.

## EXCHANGES.

**The Mining World, May 15, 1909.**—"Tin in the Black Hills of South Dakota" is the title of a paper by Jesse Simmons. In the year 1877 Prof. Richard Pearce recognized cassiterite in black sand sent him by a placer miner operating in the Black Hills. Since that time the possibility of discovering tin in workable quantities has never been absent from the thoughts of Black Hills miners. Many abortive attempts were made to exploit the Black Hills deposits. In 1891 the Harney Peak Co. was organized. After squandering several millions of dollars, this company, which was supplied with a large amount of British capital, was placed in the hands of a receiver, Dr. A. R. Ledoux. Dr. Ledoux has gradually weeded out the worthless claims, and patented the more valuable. Under his careful administration the whole enterprise has been reorganized. A sufficient amount of capital for development and equipment of the mines has been placed in Dr. Ledoux's hands, and, under his direction, work has been commenced again. The tin veins of the Black Hills are of typical granitic character, undoubtedly of eruptive origin, following closely the bedding planes of the enclosing schists. Usually the veins are lens-shaped, successive lenses occurring upon the line of strike. Many of the veins are of a true vein or tabular form, and can be traced for thousands of feet. They vary greatly in width, sometimes a few inches, and from that up to 100 feet or more. The cassiterite occurs irregularly, and is more evenly distributed through the veins from wall to wall;

but apparently lies in zones or sheets that do not appear to have any definite relation to either wall.

The veins are composed of typical gneiss, or granite with the feldspar wanting. They nearly always carry considerable percentages of columbite, tourmaline, and mica.

**Mining and Scientific Press, May 15, 1909.**—D. H. Stovall contributes to this issue a paper on blasting and preparing the shots. In the opening paragraph he refers to a mine superintendent who has made it a practice to question every miner he employs regarding his familiarity with blasting. This preliminary has helped to do away with many accidents.

**Economic Geology, April, 1909.**—In an article entitled "Some Features of the Alaskan Tin Deposits," Adolph Knoff touches upon some of the difficulties encountered by those who prospect for that metal in Alaska. The American prospector is not familiar with tin ores and tin mining. As tin-bearing rock occurs throughout the region in a great variety of ways, his perplexity is increased. Many locally occurring minerals are easily confounded with cassiterite, which itself is a difficult mineral to identify with certainty. The following species have been mistaken for cassiterite: garnet, black tourmaline, the porphyritic augite

of some quartz porphyry dikes, pyroxene in contact-metamorphosed limestone, smoky quartz, vesuvianite, magnetite, and wolframite. The belief that stannite is a highly desirable ore of tin has occasioned useless prospecting, certain sulphides, principally pyrrhotite, being mistaken for that mineral. Another widely accepted idea is that tourmaline is an infallible indication of tin ore. This belief has arisen because of the occasional resemblance between the two minerals, and also because of their close association in tin deposits in other countries. But the conclusion is unsafe.

The sedimentary rocks of the tin region comprise chiefly limestones and slates, overlain conformably by a great volume of thin-bedded, dense-textured Ordovician limestone, which generally shows no evidence of metamorphism. Four stocks of quartzose, orthoclase granites, of coarsely granular porphyritic habit, are intrusive into the limestones. Greenstones of diabasic character are common in the slate area near York, and are, apparently, intruded sills. The youngest igneous rocks are narrow basalt, dikes are found cutting both limestone and granite.

The granites have invaded the various series of limestones and produced an extensive development of lime-silicate rocks, limited as a rule to a narrow zone encircling the granite masses.

Tin ore occurs in both lode and placer form. Cassiterite is the only mineral that is likely to prove of economic value, stannite and the two new magnesian iron-tin borates being probably not worth exploitation. Cassiterite occurs in Seward Peninsula in a variety of ways, only two of which are standard modes of occurrence. These are, first, in tourmalinized margins of granite masses and granitic dikes, and, second, in quartz veins cutting granite and accompanied by impregnation of the wall rock.

**Mines and Minerals, May, 1909.**—The leading article in this number of *Mines and Minerals* is a description of the equipment and work of the Technical Branch of the U. S. Geological Survey. The Fuel Division has now been moved to Pittsburgh, where investigation is being conducted in the direction of fuel economy, producer gas, coking, washing, briquetting, and other lines. The inspection of fuels is another important branch. Mine-accident and mine-waste investigations are given special attention. The mine-explosion, research work and rescue-apparatus training are directed by Mr. J. W. Paul. Two or more sets of each kind of rescue apparatus have been purchased and are in use at the Pittsburgh station. The object of this installation is entirely educational. From two to six men are always in training under Mr. Paul. Eight hours per day are devoted to each man's instruction for two weeks. The men are selected by the coal companies, and are sent to the station and maintained there at the expense of the coal companies. After completing their period of training they are expected to return to their places of work and there act as leaders in imparting instruction in rescue-work.

#### PERSONAL AND GENERAL.

Mr. O. N. Scott has returned to Toronto after an extended professional visit to Cobalt.

Mr. R. Livingstone, late Assistant Mines Inspector of Alberta, has been appointed Chief Inspector in place of Mr. Norman Fraser, resigned.

Mr. F. A. Ross, manager of the Daly Reduction Co., Hedley, B.C., has gone to New York on a business visit.

Mr. Frank Ross, of Quebec, and Mr. W. D. Ross, of Toronto, have been elected directors of the Nova Scotia Steel Company.

Mr. J. W. Astley, of Victoria, B.C., is on a trip to Cobalt and Gowganda, with a view to following professional work there.

Prof. William Nicol, of the School of Mining, Kingston, has offered to give \$40,000 for the erection of a new mineralogy building.

Capt. W. H. Jeffrey, of the McKinley-Darragh mine, Cobalt, is taking a two weeks' business trip to Toronto, Cleveland and Cincinnati.

Dr. Milton Hersey, of Montreal, has given \$10,000 to the metallurgical department of the faculty of Applied Science of McGill University.

Mr. Norman Fraser, formerly Inspector of Mines of Alberta, has been appointed superintendent of the Crow's Nest Pass Coal Company's Michel colliery.

Mr. J. B. Tyrrell has moved his office from 9 Toronto Street to lighter and more commodious rooms in the Confederation Life Building, Richmond Street East, Toronto.

Mr. Rex Taylor has been appointed manager of the Right of Way mine, succeeding Mr. Joseph Houston, who resigned recently to take charge of the claims owned by Messrs. Sifton and O'Brien.

Mr. A. R. Wilson has resigned as superintendent for the Maple Leaf Coal Company, Frank, Alta., having been appointed a coal mine inspector by the Government of Alberta for the district east of Lundbrek.

Prof. Emmons, of Boston, Mass., one of the most distinguished members of the United States Geological Survey, paid a visit to Cobalt recently, accompanied by Mr. Benj. Lawrence, consulting engineer of the Kerr Lake mine.

Messrs. R. M. Atwater, Jr., Robert Linton and R. de Sallier have been examining the Dominion Copper Company's mining properties in the Boundary district for the protective committee of dissenting stock and bond holders, who are opposed to the reorganization scheme of the majority.

## Industrial Notes.

**Westinghouse Distributing Transformers. Circular No. 1502, April, 1909. Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa.**

All of the Westinghouse publications are of a high order of merit. This one is no exception.

Electrical energy for light and power service is supplied to the customer at several nominal voltages. Different distributing voltages create a demand for transformers of various transforming ratios. Sometimes customers are found near high voltage feeder lines exceeding 16,500 volts. In such cases it pays to install a single transformer of suitable voltage ratio.

All distributing transformers must operate under very severe conditions. Therefore the design and construction are vital considerations. The catalogue before us throws ample light upon these subjects.

The circular contains much valuable information on alternating current distribution covering transformers, lightning arresters, insulators, cross arms, etc. Considerable space is devoted to underground and overhead construction applicable to congested and scattered districts. There is also given information on potential regulating systems. The circular contains 52 pages of information of value to any central station man or any other connected in any with the distribution of power by alternating current lines.

### A NEW MINING THEODOLITE.

Ainsworth's New Theodolite.

Wm. Ainsworth & Sons, Denver, Colorado, U.S.A., have just placed on the market a new theodolite for mountain and mining work, as shown in the illustration herewith.

By the use of the hardest bronze alloys the weight of this instrument has been reduced to a minimum without sacrificing rigidity, and the U or theodolite standard, the merits of which are now well recognized, is so designed as to admit of placing a  $2\frac{1}{4}$  inch compass in the centre, which is sufficient for checking.

It has a  $4\frac{1}{2}$  inch limb and vertical circle with edge graduation, 8-inch 20-power main telescope, 7-inch 18-power auxiliary telescope with counterweight that may be used either as a top or side telescope, 4-inch 30-seconds telescope level, stadia, gradienter, magnetic variation circle, 4-screw leveling head and extension tripod. The instrument only, weighing but nine pounds, complete with all attachments.

The limb verniers are placed at 30 degrees with the line of sight, which together with the edge graduation on the vertical circle enables an operator to read both vertical and horizontal angles from the one position.

The telescope tubes are finished in an improved manner, insuring perfect collimation for all distances. Only the highest grade lenses ground according to the latest formula, are used. The telescope axis has the usual grooved bearings common to all this firm's instruments, the merits of which are now well recognized.

The leveling head is of improved design and accurately constructed so that it cannot be cramped in any position, which greatly reduces the wear on the leveling screws and renders it unnecessary to loosen all of the screws when leveling up. The plumb centre has a movement of half an inch to permit locating plumb bob over point.

The graduations are, with the exception of the compass circle, on solid silver and produced in their new 30-inch automatic dividing engine, which machine, it is claimed, is capable of producing automatically circles accurate to within one second of arc.

The instrument is fully described in their catalogue, BX-16, just issued.

## SPECIAL CORRESPONDENCE

### NOVA SCOTIA.

Glace Bay.—Now that the shipping season is fairly under way and all the collieries are working steadily, the unrest among the mining population which has been caused by the active propaganda of the U. M. W. A. has largely disappeared. The mines are working full time and obtaining good outputs, although the production remains below that of last year. The Dominion Coal Company's output to the end of May, 1908, was 1,585,364 tons, whereas to the end of May this year it will not exceed 1,260,000 tons, a decrease over the period of approximately 325,000 tons.

It was stated by the U. M. W. A. leaders that President Tom Lewis would visit Cape Breton somewhere around the 24th to review the situation and strengthen the hands of the propagandists, and preparations were being made to impress the public by means of a demonstration and procession of the U. M. W. A. following. It is now stated that Mr. Lewis is not likely to visit Cape Breton in the near future. Indeed, it is quite possible that the P. W. A. may take the aggressive and invade the territory of the U. M. W. A. A good many of the miners in the West are more than a little disgusted with the manner in which their affairs

have been run by the officers of the U. M. W. A., and the miners at Crow's Nest Pass, for example, do not view with overmuch relish the extraordinary levies that are being made upon them to support the useless strike that is being carried on by Mr. Sherman. The question of joining the Western Federation of Labour has been discussed among these men, but a good many of them come from Nova Scotia, and they are wishful to affiliate with the Provincial Workmen's Association, or at least to model their unionism upon this pattern. It would almost seem as if the time were ripe for Canadian miners to follow the national lead and assert their unity as a body of specialized workers forming part of the Canadian nation. As we have stated before, the U. M. W. A. is a body composed largely of reactionaries, and is many years behind the spirit of the times in Canada. The Canadian legislator does not seek the advice of Washington, nor need the Canadian miner seek the leadership of Indianapolis. We think that everything in Canada should partake of the national spirit, and labour unionism is not an exception to the rule.

**The New Mines of the Dominion Coal Co.**—The Dominion Coal Company are now very actively proceeding with the opening up of their large coalfield in the Lingan-Victoria Basin.

Dominion No. 12 is now to be classed as a producer, and within two months will be putting out between 400 and 500 tons a day. The new bankhead is all completed and the machinery has had several trial spins. All the colliery buildings are complete, and the underground development is well advanced. This mine is to be worked by the "room and pillar" system, the coal being hauled to the levels by back-balances, or gravity haulages. The pitch of the seams is greater than on the Glace Bay side, and it is probable that this system will be followed at all the projected mines in the Lingan Basin. One effect will be to lessen the number of horses required.

Dominion No. 14 is now at about the same stage of development that No. 12 was in at this time last year. The construction of the permanent bankhead is proceeding, and it is anticipated that No. 14 will become a producer in the summer of 1910.

The site of No. 15 is now fixed, and the work of developing the slopes will be commenced this month. The temporary plant will shortly be moved from No. 14 to No. 15, and it is expected this mine will be in a position to commence permanent construction in the spring of 1910.

**The McGill Summer School of Mining.**—About 22 students from the Mining Department of McGill University have visited the Glace Bay mines during the week ending the 15th, under the guidance of Dr. Porter. The young men were distributed around the collieries, and must have greatly profited by what they saw. It is not often that a mining student has the opportunity of seeing an entirely new group of collieries under construction, and there are a good many features of special interest around the Glace Bay mines.

**Steel and Coal.**—The Dominion Coal Company's accountants are now examining into the unpaid portion of the claim of the Dominion Iron & Steel Company under the recent decision of the Court of Appeal, with a view to the final settlement. Under the arrangement made between the two companies the figures of the claim are subject to confirmation by actual examination of the Steel Company's book and vouchers.

Under the much-invoked contract the price to be paid by the Steel Company to the Coal Company for coal is subject to revision at the end of each five year period. The first revision will fall due on the 1st of July next. The cost of mining, owing to increased wages and the enhanced prices of materials, has very largely increased in recent years, and the effect of the contract provisions will be to make the price of coal to the Steel Company for the ensuing quinquennial period higher than the price which was agreed upon for the first five years of the contract.

**The Nova Scotia S. & C. Co.**—It is understood the executive officers of the Nova Scotia Steel & Coal Company who have been in London for some time in connection with the raising of new capital, have been successful in their mission, and that the new financial scheme will be placed before the shareholders on the return of these gentlemen from England.

The Department of Labour have not as yet granted the request of the U. M. W. A. for a Board of Conciliation to adjust alleged grievances at the No. 3 Colliery of the N. S. Steel Co. It is understood the department awaited the return of the Steel Company's directors before granting the application. One of the grievances urged by the U. M. W. A. is the introduction of safety lamps without compensation to the miner for their use. It would seem more in order to ask for a commission in lunacy to inquire into the sanity of men who urge the introduction of safety lamps as a grievance. If the U. M. W. A., after much searching, can find no greater injustice on the part of the N. S. Steel Company than the introduction of safety lamps in the place of open lights, it looks as if there was really not very much wrong at Sydney Mines.

The general introduction of safety lamps into Nova Scotia mines is a very pleasing sign of the times. There is now not a

single colliery of any importance in Nova Scotia in which the use of naked lights is allowed, and we hope before long to see safety lamps made compulsory in all coal mines in Nova Scotia, no matter what the conditions. It is further to be hoped that naked lights in coal mines will be prohibited throughout the entire Dominion. It is better to be sure than sorry.

## QUEBEC.

A plant to test the value of placer gold deposits in the body of the stream near Marbleton is reported about to be installed, and mining experts have been over the ground and further developments are expected.

The D'Israeli Asbestos Mining Company have broken ground and are about erecting a plant a short distance from D'Israeli station, including siding to their works.

Chrome mining at Lakeside, near Black Lake, shows a lull at the present time, and the outlook not as extensive as formerly, but is understood that improved mining operations will be established there soon.

The Robertson Asbestos Company, at Robertson Station, have built their mill, and are now installing plant. The Shawinigan Electric Power Co. will supply the power.

The Shawinigan Electric Power Co. have extended their power to East Broughton and established a distributing station there.

At East Broughton the new mill of the Frontenac Asbestos Co. is nearing completion, and the mines and mills are expected to be in full operation about the middle of the summer.

The Broughton Asbestos Fibre Co. are now working, and the Eastern Townships Co. and Boston Asbestos Co. will commence operations about the first of June.

The Quebec Asbestos Co. have sold their mills and plant to the Ling Asbestos Co. of New York. The property is being refitted with an electric plant, the pits have all been cleared out, and operations will be commenced in a few days.

Rich deposits of copper ore are reported to have been found on the Chaudiere Valley of the Quebec Central Railway. Mr. Pennington, M.L.A., is president of the company that is organized for the working of this property.

The Quebec Central Railway are now building 30 miles of New line from St. George, Beauce, following the River Famine to the watershed of the St. John River close to the boundary of the State of Maine. It will be remembered that considerable quantities of gold have been taken out of the Famine River in years past, and it may be that further operations in placer mining along the Famine Valley will be resumed owing to the greater facilities which will be found by this line.

Reports of asbestos deposits come from the Township of Panet, County of L'Islet. This will be on the proposed further extension of the Quebec Central Chaudiere Valley Line in the direction of the Temiscouata Railway.

## ONTARIO.

**Cobalt.**—One of the most interesting sections of this camp is in the locality of Peterson Lake, where a number of companies are operating claims leased from the Peterson Lake Mining Company. This company's holdings consist of 208 acres, located under Peterson Lake, and having a narrow strip of land, originally about 33 feet in width above high water mark. The subsequent lowering of the waters of the lake materially increased the land area. By the terms of the contract with the holding company, the leases are to run five years, and during that period the company receives 25 per cent. of the gross value of the ore mined. The leases are also conditional upon the proper develop-

ment of the different properties. This insures a systematic exploration for the valuable minerals. Among the most important of the operating companies are the Brydge Syndicate, the Cobalt Leases, the Little Nipissing, the Gould Consolidated and the Kerrey Mining Co. These companies are rapidly developing their holdings in order to get the greatest amount of ore possible before the expiration of the leases, and some of them have large plants in operation.

Negotiations have now been concluded whereby the Argentum Mines Company, Ltd., a flotation of the Nevins interests, which have control of the Cobalt Central, will assist in the development of the Foster, twenty-five thousand dollars having been pledged to carry on the development work on the latter property. Arrangements have also been made for the treatment of the low-grade ores and dump of the Foster in the mill of the Cobalt Central. A flat treatment rate per ton will be charged, and the resulting profits will be equally divided between the Argentum and Foster Companies. The arrangements also include a five-year lease on the Foster.

The Warner property, a 20-acre claim located north of the Kerr Lake, is to commence operations, and in a short time a force of men will start surface prospecting. The property is controlled by a Montreal syndicate, and will be known as the Imperial Crown Mines, Limited.

The Crown Reserve have completed the sinking of a 100-foot winze from the main vein at the 100-foot level, and are now drifting in both directions. This is now the deepest working of the mine, practically all the other workings being at a depth of 100 feet. At the lower level the vein shows good widths and values. The No. 1. cross-cut, in which six high-grade veins were located, has been driven to the other side of the lake, a distance of over 500 feet. The No. 2 cross-cut, which is being driven toward the eastern boundary, is in over 450 feet, and has already cut several veins. On one of these a winze has been sunk 25 feet, and will be continued 75 feet more, at which depth drifts and cross-cuts will be run. A new bunkhouse sufficiently large to accommodate 100 men is being erected. It is generally understood in the camp that a higher output will be maintained by the Crown Reserve in the future. A total force of 155 men is employed on the property.

Mr. H. D. Symmes, of the Hydraulic Power Company, has purchased four more machine drills for the work at Ragged Chutes. Operations will be pushed as rapidly as possible in order than the plant may soon be ready to supply power. The contract for hauling the pipe has been placed, and it is now being distributed over the line, and is being welded.

The directors of the Eastern Townships Mine, which was formerly known as the Old Chap, located near the head of Cross Lake, have decided to resume operations on the property. A small steam plant will be installed to do the preliminary development work. Mr. Brown, of the Silver Cross, has been appointed consulting engineer.

A new vein of high grade ore has recently been located on the Drummond property by the diamond drill. Several holes at different angles have been bored to prove the vein, and in every case high values were encountered. The vein is about six inches wide.

A large number of the mines have resorted to the use of the diamond drill for prospecting, and at the present time there are seventeen drills working in the camp. A total average of about six thousand feet a month is being bored.

A new strike has been made at the King Edward Mine, the ore body being encountered at the seventy-foot level about four hundred feet west of the shaft. The vein matter consists of galena, bornite, calcite and native silver.

The Coniagas have been carrying on work for some time in their smelter at Thorold, perfecting their system of ore treatment, and at last have their process in such a satisfactory

working condition that they will soon be in the market for the smelting of Cobalt ores in competition with the other smelters. At the mine everything is in good shape, the only drawback being that the mill is hardly of sufficient capacity to handle the ore that is taken from the various workings. The veins are narrow but rich and the values are scattered over a good width, so much so that in one place they are stoping thirty feet wide. Very little stoping is done, most of the ore coming from development work. Of the various workings of the mine, having a total length of over seven thousand feet, there is only one that is unproductive, and it is thought that if this working is driven a few feet further ore will be encountered. The ore reserves of the Coniagas are very large, being exceeded, perhaps, by only two other mines in the camp. The new two hundred and fifty horsepower gas producer, installed a short time ago, is giving satisfaction.

New discoveries of high grade veins are reported on the Bonsall and Big 6 claims in the Miller Lake district.

While trenching on the Farah property a new vein of cobalt and native silver was discovered. The vein is about one hundred feet from the No. 1 shaft, which is now down in the neighborhood of one hundred feet. A crosscut to tap the ore body at this level will be started almost immediately. About fifty men are employed at the present time and the work is being vigorously pushed.

The Council of the Township of Coleman have voted a large sum of money to be spent in improving the roads during the coming summer. The principal work will consist of grading and putting in shape the road through the Nipissing property on the east side of Cobalt Lake, and as far out as the Savage Mine. Considerable work will also be done on several others of the more travelled roads. It would meet with universal favor if the T. & N. O. Railway or the town of Cobalt would pay some attention to the road around the railway. This section is a disgrace, there being easily nine inches of mud, and the immense number of teams hauling freight and ore keep the spot in little better condition than a quagmire.

At the Cobalt Lake development is confined to the workings from the No. 6 shaft, where there are now only two drills at work. A winze is being sunk from the crosscut and when a depth of fifty feet is reached the crosscut will be continued from that level. It is hoped that one of the McKinley-Darragh veins that showed high silver values at the two hundred foot level will be encountered in the working.

The development of the Lawson property by the La Rose is being watched with great interest, and there is much speculation as to whether or not the famous "silver sidewalk" will show corresponding values at depth. The property is being developed from the old shaft sunk by the Silver Leaf and a drift is being run on the vein at the one hundred and ten foot level. Running at right angles to the famous vein and to the south of the roadway a new vein equally rich was discovered while trenching. The new find was traced for some distance and promises to become a good producer.

The Little Nipissing have struck high-grade ore in their main vein on the Peterson Lake Lease, at the one hundred and sixty foot level. Previous to this considerable drafting had been done but the ore encountered was of low grade.

Another deal for properties in South Lorraine has been put through whereby a Haileybury syndicate has purchased four forty-acre lots known as the Finnessey claims. A force of men will be started to work in the course of a few weeks.

A contract has been let by the Cochrane mine to sink the shaft another 75 feet from the 135-foot level. At a depth of 145 feet in the shaft the diabase rock underlying the Keewatin was located.

The development of the veins in the Huronian slates underlying the diabase in the Big Pete mine of the Cobalt Central

gives the most promising showings so far found on the property.

Mr. R. Taylor, formerly of the Kerr Lake, has been appointed manager of the Right of Way, in place of Mr. J. Houston, who has resigned to take charge of the Bonsall claim, owned by O'Brien and Sifton. Mr. Houston will be retained by the Right of Way in an advisory capacity.

The appointment of Mr. Chas. Watson as superintendent of the Chambers-Ferland has been made permanent. Mr. Watson was formerly with the Nipissing, and his duties at that mine will be taken over by Mr. H. McKee.

According to present indications, the river navigation between Elk Lake and Latchford will be open about May 17th. The Upper Ontario Steamboat Company will operate seven passenger boats and also a number of scows to handle the freight. The first trip of the season was made on the 10th, when a boat went as far as Pork Rapids. Later the route was extended to Mountain Chutes. On each trip the boats were crowded with prospectors and their canoes. When the regular service is installed two return trips daily will be made between the two towns.

The shaft on the property of the White Syndicate, formerly known as the Canadian Ores, Limited, is down 145 feet, and from the bottom a drift has been started on a calcite vein carrying silver values. On this vein this drift will be driven a distance of 200 feet, when it is expected that the main vein of the property will be encountered. Four hundred sacks of ore have been taken from an open cut on this vein. A force of 35 men is at work on the property.

The Right of Way has declared a 10 per cent. bonus, to be paid on the 20th of May. Up to the present for this year the mine has produced 700,000 ounces of silver, and from present indications the company will be able to continue their disbursements to the stockholders at the rate of 5 per cent. per month.

On May 5th the first shipment of gold ore from Munroe Township was made by the Guelph Mining Syndicate. The shipment consists of four tons, and was sent to the Kingston School of Mines for a sample run. Recent developments in this district have added greatly to its possibilities of becoming a gold producer. The veins as a whole are small, but carry high values.

Work is under way on the erection of a new concentrating mill at the Colonial Mine.

Mr. John Harris has severed his connection with the Victoria mine.

Following the great rush of the past winter, the mines of Gowanda are settling down to serious work. The most essential need at the present time is a railroad, and until this is built the camp cannot make very great headway. So far the deepest working is on the Boyd Gordon, whose shaft is down fifty feet. One hundred bags of high-grade ore have been taken from the working. Two shafts are being sunk on the Mann claim, one being down about 25 feet, and the other 15 feet. The Bartlett has some of the most promising showings in the new district, but so far their energies have been directed towards the installation of the machinery, which they expect to have in running order about June 15th.

An important strike was made on the 200-foot level of the Beaver Mine on May 15th. A cross-cut was run from the main shaft for a distance of 50 feet, when a large quartz and calcite vein, with no silver, was encountered. The vein was drifted on, with the result that high silver values were found. The quartz in the vein has been replaced by calcite, and there is no small-tite. The vein is said to be nearly ten inches wide. At a distance of 234 feet east of the shaft a diamond drill is working on the 200-foot level. A hole at an angle of 45 degrees is being bored, and it is expected that when in a distance of about 125 feet another vein showing on the surface will be encountered.

## BRITISH COLUMBIA.

**Rossland.**—In Le Roi Mining Company affairs there is nothing definite to be said yet, but it is generally understood that Mr. A. J. McMillan, the managing director, is meeting with some considerable success in London in the arrangement of finances with which to carry out the proposed big plan of development of the company's property. It will certainly be gratifying to see the Le Roi mine undergoing a plan of thorough development from the 1,650-foot level downward, and it is to be hoped that the beginning of the work will not be deferred. There is no good reason why the smelter at Northport cannot be run at a profit, and this plant will undoubtedly be a paying enterprise under the proposed new order of things. The prime requisite, of course, is a supply of ore (self-fluxing, preferably) that will permit of operation at full capacity. Part of the plan now being worked on, along lines followed by most English companies, will be in the direction of acquiring new mines than may be developed to a profit earning point by the time the older mines are worked out. The near future will very likely witness important developments in Le Roi matters.

It is pleasing to note that the ore shipments from this camp are averaging from 4,500 to 5,000 tons per week, even though the Le Roi, which has had to give place to the Centre Star group as "premier mine of the camp," is closed down. The property of the Consolidated Company is shipping over 4,000 tons per week: the Le Roi 2, Ltd., nearly 500 tons, while during the week ending May 8, 1909, the O. K. lessees shipped 10 tons, and the I. X. L. 4 tons of high-grade gold ore. It is expected shipments will be resumed from the Blue Bird in a few weeks. One the Blue Bird a drift, from 35 feet depth in the shaft, has been driven 40 feet west and 20 feet east in galena, the ledge appearing from one to two feet wide and assaying about \$100 pr ton. On the Hattie Brown claim, adjoining, the shaft is being rapidly sunk on the main ledge, assays at this time, giving above \$20 per ton in silver, gold and lead. The Richmond claim, which is also on this galena vein is being worked by a small force. The Hattie Brown and Richmond have been bonded by New York capitalists, who are prepared to spend a goodly sum on proper development.

The partial success that South Belt mines have enjoyed recently would seem to assist in bearing out the statement of Clarence King and other prominent mining engineers, that the largest and richest mineral deposits in Rossland have not been uncovered yet, and would possibly be found in the valley of Trail Creek or in that section of the camp known as the "South Belt."

The rich ore shoot on the 900-foot level of the War Eagle has now been opened up on the 1,000-foot level, and shows up 400 feet long, and averaging 50 feet in width. Several thousand tons of ore that carried an average of \$30 in gold have already been taken from this lode, and it is estimated there is a million dollars' worth of ore yet in the stoping area.

Granby interests have not lost hope in this locality, despite the apparently poor results obtained at the Giant-California, and the Mascot claim has now been secured, and development work will immediately be commenced. If results of initial work warrant, as much as \$350,000 is available for development.

The Granby people are not making much fuss about what they are doing in an expansive way, but when one realizes they have interested themselves in promising mines in the Similkameen, Moresby Ilands, Rossland, Washington, etc., and that these mines are mostly big groups of rich copper claims, then it looks as though some of the men "in touch" thought there was a future for the red metal.

**Phoenix District.**—The continued strike of coal mines in Coleman and other points in Alberta has been the cause of a shutdown of the British Columbia Copper Company's mines and

smelter. Several hundred men are thus thrown out of employment, only a few miners being kept at work on special development. Shutdowns of this kind are expensive affairs for big mining and smelting companies. This one will probably cost the B. C. Copper Co. between \$9,000 and \$10,000 per month, to cover fixed charges, maintenance, superintendence, etc. This same rule applies to the Dominion Copper Co., Le Roi Mining Co. and other presently inoperative mines, to a more or less degree.

The development work that the B. C. Copper Co. is doing on the Athelstan Fraction and Bay mineral claims is returning very satisfactory results. A fine body of ore is ready for stopping in No. 2 tunnel, and there is a big tonnage of shipping ore in dump that will be sent out as soon as the railway spur is built in.

The Snowshoe is shipping from 2,00 to 2,500 tons per week to the Consolidated smelter at Trail. The strike situation will not affect the Consolidated M. & S. Co. of Canada, as they have several months' coke supply in storage, and get most of their fuel at Fernie, where there is no trouble. This same applies to the Granby Consolidated Company.

Dominion Copper affairs will very likely be precipitated when the property of the company is put up for sale at Vancouver on May 28. Both the Reorganization and Protective Committees claim to have the strongest backing, the former maintaining that \$518,000 out of the \$800,000 outstanding bonds have been deposited with them.

Winnipeg capitalists have made the first payment under the bond they have on the Bruce mine, near Midway. Development

is going ahead with good results, and present indications show the proximity of a big body of gold-copper ore.

Apropos of a change of policy on the part of the Daly Reduction Co., the Nickel Plate and Sunnyside properties have been undergoing a thorough sampling, the breaking of ore a times requiring a force of eighteen or twenty men. Two diamond drills are also at work. Walter Bean, of Denver, and G. P. Merrill are superintending the work in the interests of their principals.

The shaft at the Golden Zone is going down about 12 feet per week. It is now down 95 feet, and some of the best ore ever found on the property has been taken out at this depth.

**Vancouver.**—The Japanese operators of the Ikeda mine, on Moresby Island, have made a strike of 25 feet of copper ore in one of the deep tunnels. Recent assays show the ore to carry 13 oz. copper, silver 7 oz., gold \$8.50. The Japanese are, in this instance, proving themselves mining men of no mean ability but one can expect this from men who work low-grade copper deposits in their native land by methods now considered crude and they make even these mines pay.

As hinted at above, Granby interests have bonded the Contact group on Tasso Harbour, Moresby Island. The property is to be developed as rapidly as possible.

Mining men from Duluth, Minn., have bonded a rich group of copper claims at Tasso Harbour, paying \$400,000 for the property. T. Taylor and F. C. Elliott, of Revelstoke, were the seller. The purchasers, it is said, are men in close touch with the Steel Corporation. Development of the property will commence this season.

## GENERAL MINING NEWS.

### ONTARIO.

**Cobalt.**—On the T. & H. B. there are sixty men and six drills working. One of the drills is being operated in Trethewey territory on the third level. One drill is now operating on the first level, but the main activity is on the second level on the Lavel and Rice veins. The Rice drift has an ore shoot of 135 feet, and work is still proceeding on it. The ore shoot on the Lavel is about 165 feet long on the third level. There is at present about 7,000 tons of concentrating ore on the dump.

Drifting has been started from the 200-foot level of the main Crown Reserve vein. The drift is being driven east from the bottom of the old open-cut shaft, and the vein at this depth runs from six to eight inches of ore.

On the Nipissing the drifts on both the Kendall vein and vein 82 have reached the McKinley line. The second level of the Kendall is at a depth of 145 feet, and drifting has been done for 350 feet. The Fourth of July shaft is now down 200 feet, and stations are being cut on it. Shaft 64 has been sunk 200 feet with drifts at the 80 and 175 foot levels.

A new strike was recently made while drifting on the No. 4 vein of the King Edward mine. The new ore body is about four inches wide, containing native silver, with galena and bornite.

On the McDonald vein of the Kerr Lake a winze has been sunk 32 feet from the 150-foot level. The pay chute on No. 7 has been traced a distance of 600 feet, and the ore averages 3,000 ounces to the ton.

The La Rose has begun developments on the Lawson. The old Silver Leaf shaft is down less than 100 feet, and driving has been already started at the 90-foot level on a stringer that

is expected to lead to the main Lawson vein. At the La Rose mine raises are being made on the main vein. Good ore is steadily being taken out of No. 2 and 3 raises.

The Pontiac have struck the vein of their 75-foot level which they found with such high values on the surface. It is about two feet wide at the point exposed in the drift, although it does not run high in silver values, it looks very promising. The shaft of the Pontiac mine is down 75 feet.

A comparison of the Cobalt shipments by months for the first four months of each of the three years, 1906-7-8, with those of 1909, shows that the output is steadily increasing in a substantial way.

1906—January, 406.52 tons; February, 119.14 tons; March, 378.30; April, 137.20. Total—1,041.16 tons.

1907—January, 989.13 tons; February, 900.83 tons; March, 1,027.59 tons; April, 583.78 tons. Total, 3,501.33 tons.

1908—January, 1,481.27 tons; February, 1,184.53 tons; March, 1,815.27; April, 1,312.00. Total, 5,792.97 tons.

1909—January, 2,375.13 tons; February, 2,103.85; March, 2,561.78; April, 2,495.78. Total, 9,536.35 tons.

About 240 feet of drifting has been done on the 100-foot level and about 120 feet on the 200-foot level of the Badger mine. At the bottom of the shaft the vein shows about four inches wide of calcite and silver, from which some high assays have been taken.

At the 160-foot level of the main vein of the Little Nipissing mine, on the Peterson Lake lease, a 2-inch vein, which has been running fairly lean for some distance, has now come up with high values in native silver.

The new vein of the Lawson mine of the La Rose Consolidated has been stripped for 28 feet. The vein is six inches wide, and shows considerable native silver.

A rich strike was made at the Beaver mine on May 14th. The strike was made at the 200-foot level of the main shaft, 50 feet on the east drift. The vein is from 10 to 12 inches wide, and carries considerable silver values.

The Argentum Mines, Limited, have taken over the Foster mine under a five-year operating contract. The new company has perfected an arrangement with the Cobalt Central Company whereby the Foster ores will be handled at the Cobalt Central mill.

**Elk Lake.**—The Otisse orehouse is now about filled with ore, and as soon as navigation opens a shipment will be made so as to give room for the ore now being sacked. The ore now coming up from both shafts is being sorted and sacked, and the quantity is accumulating rapidly.

The Moose Horn was closed down for about ten days on account of the sinking of the foundation of one of the boilers, and the consequent breaking of one of the flanges. The damage has been repaired, and the mine is again running. The shaft is now down 125 feet, at which depth an aplite vein six inches wide has been opened up.

The Otisse Currie intends to start sinking another shaft on the northeast corner of their property. The present shaft is to be continued to the 250-foot level, with cross-cuts at the 150 and 250-foot levels.

A corduroy road is being laid from Elk Lake to Gowganda, so there will be no necessity for prospectors to follow the long canoe route if they wish to make a quick and light trip.

#### ALBERTA.

**Coleman.**—The striking coal miners have applied for a Board of Arbitration under the Lemieux Act. This step is rather unexpected, as Sherman, the leader of the strikers, has personally condemned the Lemieux Act. The action of the miners is said to be largely due to the attitude of the International officers.

Frank Sherman has been named as the representative of the men on the board.

#### BRITISH COLUMBIA.

**Rossland.**—There already has been between 2,000 and 3,000 tons of ore extracted from the big ore shoot on the ninth level of the War Eagle. It is about 400 feet long and 50 feet wide, and the ore runs from \$20 to \$30 per ton. A downward continuation of this ore shoot has been located on the tenth level, but its dimensions have not yet been determined.

Development of the Blue Bird continues to show up considerable ore. Drifts have been run from the shaft at a depth of 35 feet both east and west. The west drift is 40 feet in length, and the east is 20 feet. Both are in galena ore from a foot to two feet in width. Another ledge, 50 feet away from the main lead, has been stripped and opened by shallow shafts. It is from two to four feet wide, and carries galena ore of a good grade.

**Greenwood.**—The Board of Conciliation and Arbitration to inquire into the differences between the B. C. Copper Co. and its employees is meeting daily. Judge Wilson, of Cranbrook, is chairman of the board. E. G. Warren is representing the company, and Geo. Heatherton the union. The investigation will probably last a couple of weeks.

**Phoenix.**—It is the intention of the Granby Company to resume shipments from the Gold Drop about the middle of May.

The work of enlarging Nos. 3 and 4 furnaces at the Granby is being rushed, and they are expected to be completed about the middle of May. This will bring the smelting capacity up to 400 tons daily.

**Vancouver.**—The properties of the Dominion Copper Company, in liquidation, will be disposed of by public auction in Vancouver on the 28th of May, subject to reserve bids fixed by the judge in chambers, in two lots. Lot "A" will consist of all the company's property, real and personal, except that included in lot "B." Lot "B" will consist chiefly of supplies on hand for the mines and smelter and the benefit of a contract with the C. P. R. respecting freight rates.

## MINING NEWS OF THE WORLD.

#### GREAT BRITAIN.

Trouble is brewing in the Scotch coal trade. The masters demand that miners' wages be reduced to 5s. 6d. per day, whilst the men hold that the minimum must not go below 6s., and as the agreement hitherto existing between the masters and men has expired, a settlement may not be secured without a strike.

The coming into effect on July 1st next of the Mines Eight Hours Act will terminate the present agreement in South Wales, which under ordinary circumstances would continue until March 31st, 1910. So far, all efforts to reach a new agreement have failed, and trouble is expected.

The production of pig iron in the United Kingdom last year was the smallest in sixteen years. The output last year amounted to 9,289,840 tons, as compared with 9,923,856 tons in 1907, and 10,149,388 tons in 1906. The decrease of 134,016 tons as shown is the greatest recorded in any one year since 1892.

#### BELGIUM.

The Cockerill Company, who own extensive steel works in Seneffe, Belgium, are installing an electric furnace. The furnace

is built on the Girod system, with one electrode, and has a charging capacity of from two to three tons of steel.

#### RUSSIA.

The Mining Department is undertaking the revision of the general statutes of the gold industry. The present law, which has been in operation since 1903, is so obscure in parts that it has given rise to many misunderstandings in practice.

A special council has been opened in the Mining Department to consider the proposals to regulate the platinum industry in Russia.

#### AUSTRALASIA.

The Federal High Court has sustained the principal factors of the Federal Arbitration award in the Broken Hill Proprietary Company's appeal relative to the dispute with the employees at Port Pirie and Broken Hill, but has found against the award on the question of granting a 48-hour week at Port Pirie. The company will resume concentrating and smelting

ore at Broken Hill and Port Pirie until the completion of existing contracts.

All the leading mining companies in the silver-lead district of Western Tasmania, according to Consul Henry D. Baker, showed a diminution in their earnings during 1908, with the exception of several companies engaged in mining coal; this was the only mineral product whose value showed an increase over that of 1907.

#### SOUTH AFRICA.

Work in some of the outlying districts of the Transvaal has been much retarded this year on account of severe outbreaks of malarial fever, due, no doubt, in a large measure to the exceptionally heavy rains that have fallen, resulting in the creation of a large amount of decaying vegetable matter and other conditions generally associated with malaria.

Rand milling profits fell below 30 shillings per ton in March, or nearly nine shillings below the average for 1904, since which time there has been an almost continuous decrease.

A syndicate has been formed to work large iron ore deposits in the neighborhood of Alberstone, about thirty miles from Durban, Natal. The deposits consist of brown and purple hematites and limonite. An ample supply of limestone is said to be available.

#### UNITED STATES.

The legislature of Washington has appropriated \$50,000 for the State Geological Survey for the biennial period, 1909-10. Of

this amount \$30,000 will be used for co-operative mapping and hydrographic investigations, and \$20,000 for geologic investigations.

The miners of the Pennsylvania anthracite region have finally decided to renew the old agreement with the operators for another three years.

After a year or more of experimenting, those in charge of the electric iron ore smelter at Heroult, Cal., consider that they have made a commercial success of the project. The large new furnace was tapped for the first time last week. It is expected that the furnace will turn out about 200 tons of commercial pig iron daily.

The United States Senate has adopted the recommendation of the Committee on Finance for a duty of 25 cents per ton on iron ore. The House had placed that article on the free list, while the present law levies a duty on it of 40 cents per ton.

#### MEXICO.

The projected new mining law will probably not be introduced at the present session of the Mexican Congress. Inasmuch as the law is intended to be a codification of all existing laws and decrees, it is exceedingly broad in its scope, and touches on many points that are naturally open for discussion. It is said that the delay in enacting the law is due to the necessity of much consideration of these new points and phases.

## COMPANY NOTES.

#### APRIL STATEMENT OF LA ROSE.

The preliminary statement of production and earnings of the La Rose Mines, Limited, for the month of April, 1909, follows:—

|                                                                   |       | Silver<br>Contents. | Net<br>Value. |
|-------------------------------------------------------------------|-------|---------------------|---------------|
| April production—                                                 | Tons. |                     |               |
| Shipments . . . . .                                               | 625   | 315,544             | \$133,652     |
| On hand, April 30.....                                            | 285   | 267,913             | 123,139       |
|                                                                   | 910   | 583,457             | \$256,791     |
| Less on hand, March 31.....                                       | 237   | 313,090             | 145,882       |
| April production . . . . .                                        | 673   | 270,367             | \$110,909     |
| Estimated expense . . . . .                                       |       |                     | 26,794        |
| Net profit for April . . . . .                                    |       |                     | 84,115        |
|                                                                   |       | Silver<br>Contents. | Net<br>Value. |
| Total for 11 months, June 1, 1908, to<br>April 30, 1909 . . . . . |       | 2,732,295           | \$959,584     |

#### NORTHERN EXPLORATION CO. PAYS 280 PER CENT.

The Northern Exploration Co. of Cobalt, with a paid-up capital of \$100,000, has recently declared a dividend of 140 per cent., payable in La Rose shares, taken at a market value of \$7 per share. The company has already paid several cash dividends of 10 per cent. each.

The Northern Exploration Company's shares were originally sold at 50 cents, so that the dividend is really equal to 280 per cent. on the cash invested.

#### KERR LAKE DECLARES DIVIDEND.

The Board of Directors of the Kerr Lake Mining Company have declared the regular quarterly dividend of 4 per cent., and an extra dividend of 2 per cent. upon the capital stock of the company payable June 15th, 1909, to all stockholders of record June 1st, 1909.

#### NIPISSING'S APRIL STATEMENT.

During the month of April the Nipissing mined ore of estimated net value of \$149,789, and shipped ore of an estimated net value of \$96,492. This compares with ore mined in March to the value of \$141,623, and ore shipped to the value of \$193,845. Of the total 291,620 ounces of silver produced during April 108,689 ounces, or 37 per cent., came from the Kenda vein.

#### PETERSON LAKE CO. ANNUAL REPORT.

The third annual report of the Peterson Lake Silver-Cobalt Mining Company, Limited, has been mailed to shareholders.

At no expense to the Peterson Lake Company, a great deal of thorough work has been performed by the different lessees in the direction of proving up a large claim area.

Much of this work would probably not have been attempted by the parent company if conducting development and prospecting operations entirely on its own account.

Only two of the lessees have up to the present time produced any ore. The Nova Scotia and the Little Nipissing have been the producers, and from them the Peterson Lake Company draws a royalty of 25 per cent. in the form of net profit.

The double compartment shaft of the Nova Scotia has been sunk 240 feet. This shaft is located in Nova Scotia ground, so that, in order to tap the ore bodies now being explored on the Peterson property, the parent company would be under the necessity of sinking a shaft for itself.

The report makes no promise of dividends to stockholders as yet.

## STATISTICS AND RETURNS.

### DOMINION COAL OUTPUT.

|                    | 1908.        | 1908.            |
|--------------------|--------------|------------------|
| January . . . . .  | 314,108 tons | 200,176 tons     |
| February . . . . . | 285,649 "    | 209,656 "        |
| March . . . . .    | 346,529 "    | 253,622 "        |
| April . . . . .    | 335,829 "    | 294,017 "        |
| May . . . . .      | 335,829 "    | 300,000 " (est.) |
|                    | 1,585,364 "  | 1,257,471 "      |

Decrease, 327,893 tons.

### COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt camp, and those from Jan. 1, 1909, to date:—

|                         | Week ending<br>May 8. | Since<br>Jan. 1. |
|-------------------------|-----------------------|------------------|
|                         | Ore in lbs.           | Ore in lbs.      |
| Coniagas . . . . .      | 65,400                | 590,220          |
| Crown Reserve . . . . . | 102,816               | 1,883,935        |
| Kerr Lake . . . . .     | 122,201               | 605,643          |
| La Rose . . . . .       | 327,500               | 5,018,518        |
| Nipissing . . . . .     | 337,090               | 4,238,328        |
| Temiskaming . . . . .   | 150,060               | 993,260          |
| T. & H. B. . . . .      | 60,000                | 670,600          |

Ore shipments to May 8, 1909, from Jan. 1, are 20,121,033 pounds, or 10,060 tons. Total shipments for week ending May 8 are 1,164,867 pounds, or 582 tons.

|                                | Week ending<br>May 15. | Since<br>Jan. 1. |
|--------------------------------|------------------------|------------------|
| Buffalo . . . . .              | 42,990                 | 427,630          |

| T. & H. B. . . . .             | 64,200                 | 734,800          |
| Muggley Consolidated . . . . . | .....                  | 72,900           |

Ore shipments to May 15, 1909, from Jan. 1 are 20,777,803 pounds, or 10,288 tons. Total shipments for week ending May 15 are 656,770 pounds, or 328 tons.

### B. C. ORE SHIPMENTS.

The following are the ore shipments for the week ending April 30th and year to date:—

| Boundary—             | Week.  | Year.   |
|-----------------------|--------|---------|
| Mother Lode . . . . . | 7,140  | 139,022 |
| Granby . . . . .      | 22,542 | 313,013 |
| Snowshoe . . . . .    | 3,119  | 37,661  |
| Other mines . . . . . | .....  | 1,793   |

Total . . . . . 32,801 491,489

| Rossland—                 | Week. | Year.  |
|---------------------------|-------|--------|
| Centre Star . . . . .     | 3,591 | 51,182 |
| Le Roi No. 2 . . . . .    | 654   | 10,511 |
| Le Roi (milled) . . . . . | 260   | 9,260  |
| Other mines . . . . .     | ..... | 9,393  |

Total . . . . . 4,505 80,346

| Slocan-Kootenay—                   | Week. | Year.  |
|------------------------------------|-------|--------|
| Whitewater Deep (milled) . . . . . | 700   | 11,700 |
| Bluebell (milled) . . . . .        | 900   | 14,900 |
| Granite Poorman (milled) . . . . . | 250   | 4,100  |
| Queen (milled) . . . . .           | 420   | 6,930  |
| Second Relief (milled) . . . . .   | 145   | 2,495  |
| Nugget (milled) . . . . .          | 110   | 1,820  |
| Silver King . . . . .              | 487   | 1,465  |
| St. Eugene . . . . .               | 207   | 7,015  |
| Ruth . . . . .                     | 123   | 420    |
| Whitewater Deep . . . . .          | 110   | 757    |
| Lucky Jim . . . . .                | 214   | 214    |
| Kootenay Belle (milled) . . . . .  | 70    | 1,160  |
| Yankee Girl . . . . .              | 67    | 161    |
| Standard . . . . .                 | 33    | 321    |
| Silver Cup . . . . .               | 70    | 376    |
| Other mines . . . . .              | ..... | 6,987  |

Total . . . . . 3,906 60,815

Grand total . . . . . 41,212 632,650

### SMELTER RECEIPTS.

|                     |        |         |
|---------------------|--------|---------|
| Granby . . . . .    | 22,542 | 313,223 |

**B. C. ORE SHIPMENTS.**

The following are the ore shipments and smelter receipts for the week ending May 7th and year to date:—

| Boundary—             | Week.  | Year.   |
|-----------------------|--------|---------|
| Granby . . . . .      | 19,548 | 332,561 |
| Snowshoe . . . . .    | 1,548  | 30,209  |
| Sally . . . . .       | 16     | 77      |
| Other mines . . . . . |        | 22,754  |
| Total . . . . .       | 21,112 | 394,501 |

| Rossland—                       | Week. | Year.  |
|---------------------------------|-------|--------|
| Centre Star . . . . .           | 4,290 | 55,472 |
| Le Roi No. 2 . . . . .          | 631   | 11,142 |
| Le Roi No. 2 (milled) . . . . . | 260   | 9,260  |
| Le Roi . . . . .                | 40    | 60     |
| Other mines . . . . .           |       | 9,393  |
| Total . . . . .                 | 5,221 | 85,327 |

| Slocan-Kootenay—                   | Week.  | Year.   |
|------------------------------------|--------|---------|
| Bluebell (milled) . . . . .        | 900    | 15,800  |
| Whitewater Deep (milled) . . . . . | 700    | 12,400  |
| Granite Poorman (milled) . . . . . | 250    | 4,350   |
| Queen (milled) . . . . .           | 420    | 7,350   |
| Second Relief (milled) . . . . .   | 145    | 2,640   |
| Nugget (milled) . . . . .          | 110    | 1,930   |
| St. Eugene . . . . .               | 556    | 7,571   |
| Richmond - Eureka . . . . .        | 119    | 1,341   |
| Luck Jim . . . . .                 | 120    | 334     |
| Whitewater Deep . . . . .          | 135    | 886     |
| Silver Cup . . . . .               | 170    | 545     |
| Kootenay Belle (milled) . . . . .  | 70     | 1,160   |
| Yankee Girl . . . . .              | 65     | 226     |
| Bluebell . . . . .                 | 79     | 1,886   |
| Other mines . . . . .              | ..     | 6,235   |
| Total . . . . .                    | 3,839  | 64,654  |
| Grand total . . . . .              | 30,172 | 544,822 |

**SMELTER RECEIPTS.**

|                       | Week.  | Year.   |
|-----------------------|--------|---------|
| Grand Forks . . . . . | 19,548 | 332,771 |
| Trail . . . . .       | 7,514  | 125,016 |
| Total . . . . .       | 27,062 | 457,787 |

**RAND GOLD OUTPUT.**

The April output of gold at the Rand is officially placed at 607,101 fine ounces, valued at £2,578,804. The preliminary figures, issued on May 1 last, placed the outturn at 600,000 fine ounces.

The following table gives the output of gold at the Rand (in fine ounces) for a series of years:—

|                    | 1909.   | 1908.   | 1907.   | 1906.   |
|--------------------|---------|---------|---------|---------|
| January . . . . .  | 615,113 | 560,329 | 537,638 | 428,638 |
| February . . . . . | 565,218 | 541,930 | 493,542 | 407,668 |
| March . . . . .    | 607,500 | 574,901 | 538,497 | 443,723 |
| April . . . . .    | 607,101 | 565,832 | 537,019 | 439,243 |

**MARKET REPORTS.**

May 18th.—Connellsville coke, f.o.b., ovens:—

Furnace coke, prompt, \$1.40 to \$1.50.

Foundry coke, prompt, \$1.75 to \$1.90.

**Metals.**

May 18th.—Tin, Straits, 28.87 1/2 cents.

Copper, prime Lake, 13.25 to 13.37 1/2 cents.

Electrolytic copper, 13 cents.

Copper wire, 14.50 cents.

Lead, 4.30 to 4.40 cents.

Spelter, 5.10 cents.

Sheet zinc, 7.25 cents.

Antimony, Cookson's, 8.25 cents.

Aluminium, 22 to 24 cents.

Nickel, 40 to 47 cents.

Platinum, \$22.50 to \$23.50 per ounce.

Bismuth, \$1.75 per lb.

Quicksilver, \$44.50 to \$45.00 per 75 lb. flask.

**Tin.**—Reports for May 28th show wholesale price for tin at 29 cents.

**Copper.**—Buyers are being warned against the effect of speculation in copper. A circular distributed in London and New York points to the conclusion that copper is too high at £60, and that it is not now worth more than £48 at most. Stocks on hand amounted to about 30,000 tons at this time last year. They now amount to not less than 400,000 tons and are growing. Last year's price at this time was £57. It is now £60.

# FOR SALE

Owing to having been replaced by larger equipment, we offer, subject to prior sale, the following equipment at genuine bargains:

6 New Return Tubular Boilers, 150 H. P., 125 lbs. working pressure.

1 Second Hand Return Tub. Boiler, 80 H. P., 60 lbs. working pressure.

2 Second Hand Return Tub. Boilers, 60 H. P., 60 lbs. working pressure.

5 Second Hand Locomotive Type Boilers, 150 H. P., 125 lbs. working pressure.

2 Second Hand Ingersoll Sergeant Class A straight line Air Compressors; Steam Cylinders 24" dia.; air cylinders 26 1/4" dia.; 30" stroke.

1 Second Hand Ingersoll Sergeant Class G Duplex Air Compressor; Steam Cylinders 18" dia.; L. P. Air Cylinders 28 1/4" dia.; H. P. Air Cylinders 17 1/4" dia.; 24" stroke.

1 Second Hand Four Wheel Saddle Tank Locomotive, 42" gauge, cylinders 10" x 14"; weight 14 tons.

4 Second Hand Jeffrey 10-ton Electric Mine Locomotives, gauge 36", 75 H. P.

1 New Aldrich-Westinghouse Portable Electric Mine Pump mounted, 36 gauge; capacity 100 gals.; 300' lift; 10 H. P., 220 volts D. C. Enclosed Motor.

1 Second Hand Danville Tail Rope Haulage Plant, Hoist 4 drums 88" dia., Double engines, Cylinders 20" x 36"

1 Second Hand Danville Endless Rope Haulage Plant, Hoist 2 drums 60" dia., Double Engines, Cylinders 10" x 18".

2 Second Hand Crocker Wheeler D. C. Generators 125 V, 200 Amp. 25 K. W.

1 Second Hand Marble Switch Board complete with Ammeters and volt meters.

1 Second Hand 80 H. P. McEwing High Speed Horizontal Engine.

1 Second Hand 40 H. P. McEwing High Speed Horizontal Engine.

3 Second Hand Lidgerwood-Jeffrey Electric Hoists, 220 V. direct current, 75 H. P.

1500 feet Second Hand 1" wire Haulage Rope, 6 strands, 7 wires plough steel, in good condition.

10 tons 2 1/2" square soft steel—new.

400 Hadfields Steel Mine Car Wheels; 18" dia., 1 1/4" axle; bronze bushed.

**All Machinery in good Condition and will pass Closest Inspection. Immediate Shipment.**

## Amatite ROOFING

### SEND FOR A FREE SAMPLE

If you will write to-day for a free sample of Amatite, the end of your roofing troubles is in sight. It is the one roofing that needs no painting after it is once laid on the roof.

If you would sit down and figure out exactly how much it cost to paint a smooth surfaced roofing during its life, you would find that the cost of this paint is more than

the roofing itself.

Amatite, on the other hand, has a real mineral surface, and we sell the goods on the broad statement that it needs no painting of any kind.

The man who puts Amatite on his buildings is insured against leaks and trouble for many years to come.

Send name and address for a sample and booklet, which will prove conclusively how much better Amatite is than the old-fashioned "rubber roofings" which require constant painting and care to keep them tight.

# NEW BOOKS on MINING, METALLURGY POWER GENERATION

## Principles of Mining

Valuation—Organization—Administration

Copper, Gold, Lead, Silver, Tin and Zinc

By Herbert C. Hoover, E. M.

200 pages, 6 x 9, illustrated, \$2.50 (10/6) net postpaid

Published April 1909

## A Manual of Underground Surveying

Loyal Wingate Trumbull, E. M.

Consulting Mining Engineer; formerly Professor of Mining, University of Wyoming; formerly United States Deputy Mineral Surveyor for Colorado

Over 250 pages, 6 x 9, fully illustrated, \$3.00 (12/6) net postpaid

## Mining Methods in Europe

By Lucius W. Mayer  
Mining Engineer

170 pages, with many illustrations, \$2.50 (10/6) net, postpaid

This book places the latest information at the disposal of mining engineers and mining men. It is a most valuable piece of work and of the greatest importance to the mining man who seeks more economical and practical methods.

The illustrations from photographs taken in the mines by the author are a striking feature.

## The Study of Ore Deposits for the Practical Miner

With descriptions of Ore Minerals, Rock Minerals and Rocks.

A Guide to the Prospector.

By J. P. Wallace, M.D., E.M.

Member of the American Institute of Mining Engineers, and the Colorado Scientific Society

Over 350 pages, 6 x 9, with over 100 illustrations, cloth \$3.00 (12-6) net

Leather edition, pocket size, thin paper, \$3.50 (15s) net

## McNeill's Code

(1908 Edition)

\$13.00 net postpaid

This new edition does not contain a single code word appearing in the former edition. It is brand new, with a great many additions and is the best general code offered.

It covers the mining field with the greatest thoroughness and meets all requirements of all business. It is three times as large as the old edition.

The terminal index is embodied in this code.

## Notes on Metallurgical Mill Construction

Edited by Walter Renton Ingalls

256 pages, 6 x 9, cloth, \$2.00 (8/6) net postpaid

A New, One-Volume Edition of

## The Nature of Ore Deposits

By Dr. Richard Beck

Professor of Geology, Mining Academy, Freiberg

Translated and revised by Walter Harvey Weed

Formerly published in two volumes. Now issued in one volume.

\$6.00 (1£5s) net postpaid

## Millwrighting

By James F. Hobart, M. E.

400 pages, 6 x 9, fully illustrated, \$3.00 (12/6) net postpaid

(Published March 1909)

## Notes on Lead and Copper Smelting

Revised to November, 1908

By Hiram W. Hixon

162 pages, 6 x 9, \$3.00 postpaid

## Copper Mines of the World

By Walter Harvey Weed

Price \$4.00

## Principles of Copper Smelting

By Edward Dyer Peters

Price \$5.00

## The Metallurgy of Steel

By Bradley Stoughton

Price \$3.00

## The Manufacture and Properties of Iron and Steel

By Harry Huse Campbell

Price \$5.00

## A Manual of Fire Assaying

By Chas. H. Fulton

Price \$2.00

## Hydrometallurgy of Silver

By Ottokar Hoffman

Price \$4.00

## The Electric Furnace

By Alfred Stansfield

Price \$2.00

## Mining, Mineral and Geological Law

By Chas. H. Shamel

Price \$5.00

## Mine Timbering

By Sanders, Parlee, Macdonald and others

Price \$2.00

## Simple Mine Accounting

By David Wallace

Price \$1.00

## The Gas Engine

By Cecil P. Poole

Price \$1.00

## Gas Power

By F. E. Junge

Price \$5.00

## Producer Gas and Gas Producers

By S. S. Wyer

Price \$4.00

## Tulley's Handbook on Engineering

(Steam and Electrical)

By H. C. Tulley

Price \$3.50

## Motor Troubles

By E. B. Raymond

Price \$1.50

## Steam Turbines

By Lester G. French

Price \$3.00

## The Power Handbooks

Per volume \$1.00. Monographs on the following subjects:  
Shaft Governors Pumps Shifting, Pulleys and Belting  
Erecting Work Knocks and Kinks Engine-Room Chemistry  
Boilers Pipes and Piping Steam Turbines

## The Copper Handbook, Vol. VIII.

A Manual of the Copper Industry of the World

1,500 pages, 5¼ x 8½, price \$5.00

## Mineral Resources of Canada

140 pages, 7½ x 9½; 32 color engravings; mineral map of Canada  
Price: paper \$1.00, cloth \$1.25

## The Dominion Coal Company

An Historical and Descriptive Brochure

By F. W. Gray

Price \$1.00

## IMPORTANT BOOKS IN PREPARATION

Volumes III and IV of

## Ore Dressing

By Robert H. Richards

Professor of Mining, Massachusetts Institute of Technology

2 Vols., 600 pages each, 6 x 9, fully illustrated, per Vol. \$5.00 (21/-)

net postpaid

(Scheduled for publication June 1909)

## Timbering and Mining

By W. H. Storms

6 x 9, fully illustrated, \$2.00 (8/6) net postpaid  
(Price subject to change. Scheduled for publication June 1909)

## Electro-Magnetic Ore Separation

By C. Godfrey Gunther

6 x 9, fully illustrated, \$3.00 (12/6) net, postpaid  
(Scheduled for publication May 1909)

When answering Advertisements please mention THE CANADIAN MINING JOURNAL.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

# Geological Survey

## PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects

### MARITIME PROVINCES

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

### QUEBEC

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the province north of the St. Lawrence are also available.

### ONTARIO

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

### THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

### BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

### YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

### THE NORTH-WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

*Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.*

### **THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:**

#### **NOVA SCOTIA**

- 1019 City of Halifax Sheet.  
1025. Waverley Sheet.

The above two sheets belong to the regular series of Nova Scotia map sheets on a scale of one mile to one inch. The first includes Halifax City and Harbour, the second the Waverley Gold District.

#### **ONTARIO**

1076. Gowganda Mining Division.  
This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

#### **BRITISH COLUMBIA**

1002. Geological Sheet, Special Map of Rossland.  
This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shews the geology and location of veins.  
1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch, by W. H. Boyd.  
NOTE.—Maps recently published may be had on linen cloth for use in the field at the price of 10c. per copy.

#### **REPORTS**

1072. Summary Report of the Operations of the Geological Survey for year 1908.

The Geological Survey, under certain limitations, will give information and advice upon subjects relating to general and economic geology. Mineral specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

*Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.*

# Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,  
**Toronto, Canada.**

# PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

## Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornaments and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants **PROSPECTING LICENSES** for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement.

The price of prospecting licenses is \$5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only \$2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, \$10.00 per acre, and on lands situate less than 20 miles from such a railway, \$20.00 per acre:

Superficial products and building materials are sold \$2 and \$4 an acre according to the distance from rail road.

**MINING CONCESSIONS** are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed

lands; work must be bona fide begun within two years and \$500.00 spent on each 100 acre concession.

**MINING LICENSES**, giving the right to work the mine and dispose its products, are granted on payment of a fee of \$10.00 and a rent of \$1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by poles.

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with **MR. MILTON HERSEY**, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

**The Hon. Minister of Colonization, Mines and Fisheries**  
Parliament Buildings, Quebec.

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver, \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Minerals or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579, the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

When answering Advertisements please mention **THE CANADIAN MINING JOURNAL**.

Manning Arcade, Toronto  
Fernie, British Columbia

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 1,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

Our Analyses Speak for Themselves.

WAS. SIMISTER,  
General Superintendent.

J. D. HURD,  
General Manager.

DOMINION

OF CANADA

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

W. W. CORY, Deputy of the Minister of the Interior

## **The Sullivan "WB-2" Compressors**

is the premier of the straight line type,  
combining in the highest degree the  
elements of reliability, strength and  
efficiency, sought in these machines.

"WB 2" compressors have simple  
steam cylinders, with Meyer adjust-  
able cut-off, and two stage air cylin-  
ders, with large intercooler, and the  
Sullivan air valve motion, consisting  
of rolling inlet valves, positively  
driven, and automatic poppet air  
valves.

They are built especially to com-  
press air continuously and without  
interruption, from year end to year  
end.

### CONCERNING GEOLOGICAL REPORTS.

A preliminary report on Gowganda Mining Division has been issued by the Geological Survey of Canada. It embodies the results of Mr. W. H. Collins' work during the field season of 1908.

Mr. Collins sketches carefully the general geology of the district. The typical rocks of each formation are discussed. Diabase and aplite come in for a full share of attention. An abstract of some of these pages will be found elsewhere in this issue of the Canadian Mining Journal. We wish to develop a few thoughts inspired by Mr. Collins' remarks on the economic geology of the region.

The field geologist of to-day is expected to keep ever before him the economic side of his work. It is not intended that he should usurp the functions of the prospector or of the mining engineer. Nor can he. Usually in Canada his field is so large and so new that his first few seasons must be devoted to topographic observations, rather than to pure geology.

After determining the topographic features the geologist begins to distinguish, differentiate, and correlate the formations into which the rocks of the region are resolvable.

When the geologist precedes the prospector he is too much absorbed in his duties to permit himself the relaxation of prospecting. When he follows the prospector he must regard the richest silver veins as decidedly of less value to him than a good rock exposure. Veins and other vanities must wait until the broad geological history of his territory has been ascertained. This, at least, was the attitude of the last generation of geologists. We do not mean to imply that commercial phases were totally overlooked. But the purely academic predominated.

Whilst it is apparent that the old order is changing, the readjustment is slow. Habits of thought are persistent. The geological reports of yesterday were strongly academic. To-day they are only less so. Yet the tendency to investigate and emphasize more and more the commercial potentialities of our country has been plainly evident in the operations of the Canadian Survey during the last few years. This does not mean that pure geology is being neglected. There is little danger of that. It does mean that the younger generation of geologists is being trained to correlate geological data and commercial possibilities, that a closer bond is being formed between the Survey and the mining industry.

The effort to develop the economic geology of fields old and new has brought with it complications. Canada is lustily prosperous. It is passing through a period of easy money. Mining enterprise, some of

which are sound, some that are doubtful, and many that will never go farther than the flotation stage, are being put before the public every day. Every prosperous camp or promising new region attracts its quota of reckless promoters, men willing and anxious to use any avenue to wealth. Hence it is imperative that the geologist walk with utmost circumspection when he deals with the geological economics of a new district. He may depend upon it that favourable statements will be separated from their context, that his written opinions will be garbled, and that in every way possible, his report will be used to boom the projects of fakirs.

That this has been recognized is evident from the extreme caution that marks and, possibly, mars the publications of the Ontario Bureau of Mines. It is difficult to say just how far the geologist should go. In our own opinion, while we defer to no one in our appreciation of the Bureau's thoroughgoing honesty and high technical efficiency, we believe that it could have done and can yet do much more towards exposing fraud.

We have alluded to the need of caution and to the undesirability of overmuch caution. It is pertinent to remark here that the official geologist is in danger of becoming proverbial for his skill in hedging. It is pleasing, therefore, to observe that Mr. Collins has said something definite concerning Gowganda. In this he has defied tradition. He has boldly, almost baldly, committed himself to the statement that Gowganda is a district worthy of attention. This is well.

But, while we may justly appreciate Mr. Collins' moral backbone, we may be pardoned if we qualify our appreciation by suggesting that he has fallen into one error. Several of his sentences, if quoted alone, give a quite false impression. These sentences grouped together, could be used to prove that Mr. Collins is highly enthusiastic about Gowganda—which is, of course, not the case.

This all goes to prove that the geologist, when his work impinges directly upon mining, must keep his weather eye open.

It is but fair to say in conclusion that Mr. Collins' report is singularly well written. We do not intend our mild comments to be mistaken for harsh strictures. Our purpose is rather to indicate a dangerous tendency than to exploit a fault.

#### PERMISSIBLE EXPLOSIVES.

The Technologic Branch of the United States Geological Survey is getting down to business. In addition to its labours in the direction of rescue work, it has begun to take up the question of explosives. In Great Britain and on the Continent only such explosives as appear on the "Permitted List" are used in collieries. Permitted explosives are those that give favourable results when subjected to certain tests. On the Continent, especially in Belgium and Germany, these tests are more rigid than those used in Great

Britain. But the general effect is the same. Carelessness is checked, both in the manufacturer and in the user, and human lives are saved.

Now the United States Government has waked to a sense of its duty. It has erected and equipped an Explosives Testing Station at Pittsburg. Here samples, furnished by manufacturers, are tested. A list of explosives that passed the set tests has just appeared. Seventeen brands, tested before May 15, 1909, have met with the approval of the Technologic Branch. Varying the British phrase, the United States authorities have designated these "Permissible Explosives." "Explosives Circular No. I," published by the Technologic Branch of the U. S. Geological Survey, sets forth the conditions and details of tests.

These activities are to be commended unreservedly. It would not be distasteful to us were the Canadian Mines Branch to take up this supremely important line of investigation and regulation. Canada is sadly behindhand.

#### AMALGAMATED ASBESTOS.

The public very rarely learns the full truth concerning mergers. This is especially true of mining mergers.

Shares in Amalgamated Asbestos are now being placed in the principal money markets of the world. The promoters of this particular merger claim that it controls 80 per cent. of Canada's present supply of asbestos. The facts seem to indicate that the merger actually controls less than 50 per cent.

Further inspection points to the probability that costs will be higher and dividends lower than the figures advertised.

But more serious are the indisputable facts that Russia is fast becoming a strong competitor in the production of high-grade asbestos, and that Quebec's output of high-grade is not increasing.

A careful presentation of present conditions will be found elsewhere in this issue. We bespeak for this the closest attention. Unless the statements and logic here set forth can be successfully refuted, there seems to be small hope for the ultimate success of Amalgamated Asbestos. Indeed, to the disinterested observer the whole structure appears top-heavy.

However, the reader may judge for himself.

#### A WESTERN INVASION.

An attempt is being made by the United Mine Workers of America to bring under their control the coal mines of Vancouver Island. The Victoria Daily Colonist earnestly urges the local miners to walk warily and to be sure of their ground before taking a step that would certainly disturb their present peaceful condition.

With the efforts of the United Mine Workers, in so far as these efforts are directed towards Canada, we have absolutely no sympathy. Canadian miners are perfectly able to take care of themselves. Compared

with the labour organizations of the United States, Canadian bodies are cleaner, more independent, and, consequently, much less open to the nefarious manipulation of hired agitators.

Strikes are bad enough, even when there is an honest grievance or a serious difference of opinion as between employee and operator; but when thousands of Canadian miners surrender themselves to a foreign organization that will order wholesale strikes for reasons having not the remotest bearing upon Canadian conditions, then indeed they may expect loss, humiliation, and endless strife.

### ARITHMETIC.

Our industrious contemporary, the Monetary Times, in an idle moment compiled a summary of Cobalt promotions. The totals that it arrived at were only less alarming than its own conclusions.

Records for the past four and one-half years show that 602 companies have been organized, having an aggregate capital of \$504,202,000, and an average capital per company of \$837,544. Dividend returns over the same period represent about 2 per cent. on the total authorized capitalization.

Why the Monetary Times has allowed arithmetic to smother its common sense, we know not, and we regret that some of our English contemporaries have been misguided enough to take the Monetary Times seriously.

The total capitalization shown above has no bearing whatever upon Cobalt. It would easily be possible for promoters to organize Cobalt companies whose total capitalization would run up into billions. The arithmetic employed by the Monetary Times would then bring dividend returns down to some tenuous decimal.

If the figures quoted show anything, they demonstrate the need of closer governmental control of company charters. A large majority of the companies organized to exploit Cobalt's silver never got beyond mere organization. Many of them are merely names. Only a small minority have acquired mining properties. A still smaller proportion are shipping ore and paying dividends.

All of which is so obvious that we apologize to our readers for touching on the matter at all. Our excuse is that Cobalt does not deserve the implied aspersion.

A little arithmetic is a dangerous thing.

### BRITISH COLUMBIA ZINC ORES AND THE U. S. TARIFF.

The provision of the Payne tariff that places a cent a pound on the contained zinc ores carrying 40 per cent. and over, has aroused much adverse comment in British Columbia.

A tariff reduction has been made on low-grade Canadian ores. But is impossible for British Columbia producers to ship ore carrying less than 40 per cent.

zinc at a profit. It is claimed, therefore, that the new tariff simply closes the United States markets to our western producers.

The remedy, as pointed out by Mr. Louis N. Pratt, is the erection of Canadian smelters. The only existing Canadian zinc smelter is the electric plant at Nelson. This has not yet got beyond the experimental stage. While it is hoped and believed that the plant will be successful, yet it is not proven. Meanwhile the province will have to face resolutely the problem of treating its zinc ores.

### "WHICH."

It is no longer fashionable for the mining engineer to be careless as to the language in which he clothes his reports. The time has passed when orthographic solecisms and errors in grammar reflect anything but discredit upon the writer. Yet the majority of technical men fail to pay attention to certain small but important items.

We have not time to elaborate this theme. One example will illustrate our meaning amply. Most writers, technical and otherwise, use the words "which" and "that" interchangeably, or almost so. Preference is generally given to the former word. As a matter of fact, correct usage demands the use of the latter pronoun much more frequently. As pointed out by Mr. T. A. Rickard, a safe rule is to use "that" in every possible case, using "which" only when "that" is obviously unsuitable.

### EDITORIAL NOTES.

Of fourteen representative Welsh, English, and Scotch collieries, eleven reported decreased net profits during the year 1908. The Welsh collieries suffered least. The wide foreign market that they serve placed them above the vicissitudes that hampered and distressed the Scotch producers.

Our Cobalt letter, in the Special Correspondence section, is of more than usual interest. The notes on the power developments are significant. Cobalt is entering upon a new phase of her career. The industrial element is slowly ousting the speculative.

Amongst the British Budget proposals is one imposing a tax on the owners of mining royalties. During a late debate, the Chancellor of the Exchequer pointed out that in most cases land owners demand ten times more money for surface damage than the land is worth for agricultural purposes. The mine owner and the miner contribute to many taxes. The former bears the whole responsibility in the event of failure, accident, or loss from any cause. The royalty owner escapes all risk. Even if the mine is closed he still insists on exacting a dead rent. Hence it is thought perfectly fair to call upon him to make his contribution towards the expenditure of the nation.

In the article entitled "Coinage in the British Empire" which appeared in our issue of May 15th, the author desires to explain that the gold values have been computed at the legal rate of £3 17s. 10½d. per Troy ounce standard, and the silver values at the coinage value of silver in the United Kingdom, namely, £5 6s. per Troy ounce standard. We also wish to point out that through a clerical error the sign of dollars was placed before the figures representing the number of nickel, copper, and aluminium coins turned out of the Royal Mint in 1907.

The action of Minerals Separation, Ltd., against the Ore Concentration Company, Ltd. (Elmore Vacuum),

was discontinued last month. The discontinuance was due, so the former company states, to the fact that the Ore Concentration Company's process is not now being worked commercially at any mine in Great Britain. Minerals Separation, Ltd., is, on the other hand, preparing to proceed against those who are using its processes on a commercial scale in other countries. Against these contentions the Ore Concentration Company, Ltd., advances the statements that three separate Elmore plants are working commercially in Great Britain, treating a total of 40,000 tons of ore per annum, that all the foreign patents purchased by Minerals Separation, Ltd., have lapsed, and that the latter company lost practically every step in its suit and had to pay all costs.

## THE AMALGAMATED ASBESTOS CORPORATION, LIMITED.

(Written for the Canadian Mining Journal by J. J. Harpell.)

From time to time mines and mining prospects in different parts of the world have been subjected to periods of excessive capitalization, flotation and speculation, but probably at no period has any country been so thoroughly given over to the promoter as is Canada at the present time. As soon as one section of the country is "capitalized" until the people are tired reading the advertisements and inspired articles, another section is taken up, in a manner sufficiently different to throw the unsuspecting public off their guard.

During the last few weeks the press has been giving much attention to the "Amalgamated Asbestos Corporation, Ltd." The very glowing accounts of the dividends to be earned by this venture are sufficient to inspire the uninitiated with a desire to subscribe his last dollar; while the statements setting forth how thoroughly the whole asbestos industry of the world will be in the grip of this corporation should fill the user of this material with apprehension of the prices he will have to pay in the future for his supplies.

The following is a quotation taken from one of our soberest publications, "The Financial Post of Canada":—

"... It is understood that the Canadian underwriting of the Amalgamated Asbestos Corporation is closed. The amount subscribed in Canada is over \$2,200,000. England took \$2,000,000 of the underwriting. The American lists will be closed this week.

"In a report made by Mr. Fritz Cirkel, the Government asbestos expert, he estimates the earnings at an amount equivalent to over 14 per cent. on the common stock, giving the figures as follows:—

Receipts for 74,550 tons at \$42.50 per ton. \$3,168,375  
Cost of production at \$20 per ton. . . . . 1,491,000

Total profit for the year. . . . . \$1,677,375

"He adds: 'Knowing from personal investigation in the district the great possibilities of the properties under consideration, I must state that the above

statement of receipts and expenditures is a conservative one, and I am sure that if full advantage is taken of the splendid physical conditions which present themselves for the economical operation of the British-Canadian, the Standard, and the Dominion, and if, furthermore, operating engineering skill were displayed, the cost of production per ton, which I have set down as \$20 in the above statement, will be considerably reduced.

"As to the market for the Canadian article, I may say that I have recently investigated this subject, and I find that since the year 1904 the uses for asbestos—more particularly in the United States—have been almost trebled, especially in the application for building material. This necessitated an increase in the production of all the properties in the district for the last four years of 75 per cent., while the value of the product increased almost 100 per cent. for the same period.'"

The four-page prospectus that is being circulated by the "Amalgamated Asbestos Corporation, Ltd.," contains little or none of the information that the public should have before it is asked to subscribe for stock or bonds in such a corporation. The four pages are filled largely with general statements concerning the asbestos industry and the prospective earnings of the corporation, which, in many instances are misleading.

The capitalization of the corporation is \$25,000,000, made up as follows: \$15,000,000 first mortgage 5 per cent. bonds, of which \$7,500,000 are being offered to the public for immediate subscription, the balance being retained for further requirements; and \$10,000,000 stock, of which \$1,875,000 is preference bearing 7 per cent. cumulative, and the balance being common stock. Annual payments to a sinking fund for the redemption of the bonds are to begin in 1913, and to be equal to 2 per cent. of the par value of the bonds. Thus, the fixed annual charges on the bonds now being issued will amount to \$375,000, and after 1912 to \$525,000. On the preferred stock there will be \$131,250 interest, or alto-

gether \$656,250 will have to be distributed annually before any dividends can be paid on the common stock.

The Board of Directors is composed of sixteen gentlemen, of whom three may be said to be men who have been interested in the production of asbestos. The others are mainly bankers and brokers. One of the above-mentioned three is Dr. R. V. Mattison, of Ambler, Pa., whose interest in the corporation will be referred to subsequently.

The asbestos companies that have been purchased by the Amalgamated corporation, and for which the proceeds of the \$17,500,000 of the capitalization, less \$900,000, which is to be retained as working capital, has been given, are as follows:—

The Kings Asbestos Mines, Thetford Mines, Quebec.

Beaver Asbestos Company, Thetford Mines, Que.

The British-Canadian Asbestos Co., Ltd., Black Lake, Que.

The Standard Asbestos Co., Ltd., Black Lake, Que.

The Dominion Asbestos Co., Ltd., Black Lake, Que., and the

Bell Asbestos Mines, Thetford Mines, Quebec, by a contract for the entire production of the property over and above the manufacturing requirements of the Keasby & Mathison Company, manufacturers of asbestos products, and of the affiliated companies controlled by Dr. R. V. Mattison.

In an interview which the writer had with Dr. Mattison a few days ago he was told that for some time this gentleman has been a greater purchaser than he had been a seller of raw asbestos, and that he had no intention of materially increasing the output of the Bell Asbestos Mines, but on the contrary expected to increase very largely his purchases in the future due to the requirements of the new manufacturing plant he is putting up at Shawinigan, Quebec. It would thus seem that the Amalgamated Corporation must count only on the first five companies mentioned above for their profits.

The bonds alone represent capital invested, all the stock, both preferred and common, being given away either to the promoters or underwriters. Those underwriting the bonds require to deposit only 20 per cent. of their bond subscription with the Royal Trust Company, of Montreal, which company holds in trust all the bonds and stock. The remaining 80 per cent. is evidently provided in some other way. In other words, the Trust Company, either alone or with the assistance of banks or other financial institutions, has undertaken to carry these bonds on margin until they can be unloaded on the public, in the same way that a broker would carry the stock of a client who was speculating in the stock market on margin.

The prospectus further states that according to the statement of a firm of chartered accountants who have examined the books of the companies acquired by the Amalgamated corporation, the aggregate net earnings of these companies for the last year were \$556,000. These profits, it must be remembered, are bookkeeping profits, which are often very different from profits that may be paid out to liquidate fixed charges or to pay dividends.

The remainder of the prospectus is taken up with general statements concerning the asbestos industry and the prospective earnings of the Amalgamated corporation, and winds up as follows:—

"There are three factors in this consolidation which are unique and without parallel:

"1st. There is no known substitute for asbestos.

The demand is constantly increasing and at increased prices.

"2nd. Ninety per cent. of the world's supply of asbestos comes from the Province of Quebec, and principally from Black Lake and Thetford.

"3rd. The Amalgamated Asbestos Corporation, Limited, will control 80 per cent. of the asbestos of these districts, and 70 per cent. of the world's supply."

The writer has recently returned from a trip to Europe, where he spent the greater part of two months in studying the markets for Canadian ores and minerals. Since returning he has visited the asbestos districts of Quebec. On both these trips much information and many statistics were gathered concerning the markets, uses, sources, cost of production, transportation, etc., of asbestos. In the light of these data let us examine some of the above statements of the Asbestos Corporation, as well as the figures advanced by Mr. Cirkel.

Almost every country in the world claims to have asbestos deposits, and from time to time most countries have sent more or less into the market. But the regular producers of appreciable quantities, outside of Canada, have been Italy, Russia, and South Africa. Italy has been a regular producer for years of a superior quality of asbestos. But at no time has her production been large. During the last seven or eight years the Russian asbestos deposits have experienced a very rapid development, due to the advance in the price of the crude article. The cost of production is much less in Russia than in Canada; wages are lower and the percentage of asbestos to a given area is higher. But the cost of transportation is so great that only the superior grades can be shipped. The cost of carrying the Russian material to market is from \$22 to \$25 a ton, as compared with from \$5 to \$7 for marketing the Canadian. In 1908 Canada produced 65,157 tons, of which 47,574 tons was material that on the average was worth less than \$24 a ton. This low-grade material could not have been marketed from the Russian mines. Considering these facts, there is no asbestos district in the world that has increased in the production of the superior grades during the last seven or eight years as have those in Russia. Previous to 1900 the annual output of Russian asbestos was about one thousand tons. In 1907 the output was 10,331 tons. During the same period the output of similar grades of the Canadian material has practically remained the same. In 1900 the output of Canadian No. 1 and No. 2 crude and fibre was 21,613 tons. In 1907 Canada produced 23,830 tons of these grades. In 1908 only 16,582 tons of these grades were produced by Canada—a heavy falling off. (These figures are taken from the Government returns.)

The larger increase in the demand for asbestos during recent years has been in the low grades that are generally known as "paper stock," and that sell for from \$10 to \$30 a ton. For the uses to which these grades are put there seems to be no material that suits the European manufacturer so well as the South African article. It is of lower specific gravity, and the fibre is longer and tougher. These features make it most suitable for mats, etc., for boiler and pipe covering. Owing to the constant and rapid increase in the demand for this article the development of the South African areas, in which it is found, is bound to receive special attention during the next few years and a corresponding increase in the output may be looked for.

From the above figures it will be seen that Russia is at present supplying over fifteen per cent. of the world's output of asbestos. All other countries outside

of Canada are supplying from five to seven per cent. So that Canada supplies the balance, or between 75 and 80 per cent., of which by far the larger part is made up of low-grade material.

Now let us see how much of the Canadian output will be controlled by the new merger. For this purpose we will take the actual shipments made by the companies included in the merger during the last three years. These are as follows:—

|                          | 1906.<br>tons. | 1907.<br>tons. | 1908.<br>tons. |
|--------------------------|----------------|----------------|----------------|
| Kings Asbestos Mines.... | 16,328         | 16,273         | 15,291         |
| Beaver Asbestos Company  | 1,598          | 1,901          | 2,705          |
| British-Canadian .....   | 3,155          | 4,070          | 6,327          |
| Standard .....           | 2,406          | 2,373          | 2,323          |
| Dominion .....           | ....           | ....           | 87             |
| Total .....              | 23,487         | 24,617         | 27,733         |

The total production of Canadian asbestos in 1906 was 61,675 tons; in 1907 it was 61,985 tons, and in 1908 it was 65,157 tons. So that the companies now included in the merger controlled 38 per cent. of the Canadian output in 1906. They controlled 40 per cent. in 1907, and in 1908 they controlled 42½ per cent. The Amalgamated thus occupies a position quite different from that which its promoters have claimed for it.

Now let us analyze some of Mr. Cirkel's statements. He assumes that the new merger will produce 74,550 tons. To increase their present production to this figure they will require to do one of two things; they will either have to acquire control of the whole of the Canadian output or else increase their own output up to this point. If they increase their own output and find a market for it, no doubt, in the natural course of events the other companies that are now in the field will be doing likewise, so that when the Amalgamated reaches Mr. Cirkel's figures, the whole of the Canadian output will be over twice that tonnage. To market such an output would be an impossibility for some time to come. The output has always kept pace with the demand. In fact, it has kept slightly ahead of it. Very frequently mills have had to be closed earlier in the season than they might, because of the fact that their storehouses were full, and to attempt to empty them by forcing the material on the market would mean a reduction in price below the point at which there would be a profit. The only other way by which the Amalgamated can reach Mr. Cirkel's estimate is by acquiring control of the balance of the Canadian output. But here again Mr. Cirkel's figures are upset. It requires \$7,500.00 of bonds and \$10,000,000 of stock to control 42½ per cent. of the Canadian output; how much will it take to control the whole of it? If it takes annual fixed charges amounting to \$656,250 to control 42½ per cent. of the output, it will require over a million and a half of annual fixed charges to control the whole of it. Then again his price of \$42.50 per ton is too high when it is remembered that any material increase in tonnage will be in the grades averaging under \$24 per ton. On the other hand, his cost of production is very much too low. In 1903 the cost per ton during the month of August in one of the best mines in the district was \$18.56. Considering that this was for a month which would have the maximum output of any month in the year, as well as the minimum cost, and also considering that this was for one of the best mines and mills in the district it is reasonable to expect that the average cost per ton for all the mines over the whole of 1903 was more than this. Since 1903 the cost

of production has considerably increased, largely due to the increased cost of labour.

The writer has before him sheets showing the cost of production during a number of periods. From these figures he finds that in every case the item of "wages and salaries" equals a little more than half the total cost of production. According to the returns made to the Quebec Government, the wages paid by all the asbestos mines in 1908 amounted to \$1,066,774. Twice this would bring the total cost of production in 1908 up to \$2,133,548. According to the same report, the total was \$2,577,302. On this basis the net profit on the whole of the Canadian asbestos industry would be somewhere between four hundred thousand and half a million dollars. Of this profit the companies now in the merger would receive in the neighbourhood of \$200,000.

The asbestos industry of Canada is no mint. It is only sufficiently profitable to make a good healthy business. It is true that during recent years there has been a decided increase in the demand for asbestos and a corresponding increase in the price. But the main advance in price has been for the superior grades, such as crude No. 1 and No. 2 and fibre, in which grades, it must be remembered, there has been no increase in the Canadian production. All the increase in the Canadian production has been in the lower grades of "paper stock," as may be seen from the following figures taken from the Government returns:—

|         | No. 1<br>Crude. | No. 2<br>Crude. | Fibre. | Total<br>Superior<br>grades. | Paper<br>stock. |
|---------|-----------------|-----------------|--------|------------------------------|-----------------|
| 1900... | 1,755           | 3,490           | 16,368 | 21,613                       | ....            |
| 1901... | 2,083           | 2,660           | 14,639 | 19,382                       | 14,054          |
| 1902... | 1,319           | 3,131           | 15,502 | 19,952                       | 10,682          |
| 1903... | 930             | 2,354           | 9,150  | 12,434                       | 16,327          |
| 1904... | 1,646           | 2,727           | 7,771  | 12,143                       | 23,336          |
| 1905... | 1,640           | 2,253           | 10,707 | 14,600                       | 34,655          |
| 1906... | 1,477           | 2,450           | 18,542 | 22,469                       | 39,306          |
| 1907... | 1,487           | 2,938           | 19,905 | 24,330                       | 37,655          |
| 1908... | 900             | 2,771           | 13,911 | 17,582                       | 47,574          |

In 1903 the average prices of the different grades were as follows:—

Crude No. 1, \$126.50; crude No. 2, \$110.40; fibre, \$34; paper stock, \$16.

In 1908 the average prices were:—

Crude No. 1, \$290.00; crude No. 2, \$160.00; fibre, \$52.00; paper stock, \$23.86.

These figures will indicate the cause for the very rapid increase in the production of the Russian material. The Russian deposits are extensive and exceptionally rich, but the material is not so good as is the Canadian for textile purposes. At the prices that prevailed previous to five or six years ago it could not be marketed in competition with the Canadian article. But as soon as the prices went up the Russian article began to come into the market in large quantities, and in eight years the output increased about ten times. At present the Russian No. 1 crude is selling at from \$200 to \$225 a ton. The same thing is likely to happen in the lower grades as soon as the prices of these grades reach a figure at which the Russian article can be marketed profitably. The prices for these grades will not need to advance much farther before this point is reached; because the lower grades of the Russian article compare more favourably with the lower grades of the Canadian article than do the higher grades. Then, of course, there is the South African article, which seems to be better adapted for the uses to which the so-called

"paper stock" is put than any other class on the market. Already the increased prices and the demand for this material are quickening the activities in the South African asbestos industries. These are features which the Canadian producers must take into consideration.

During the last eight or ten years the cost of production in Canada has very materially increased, and through no fault of the asbestos producers. The whole cause lies in the phenomenal advance there has been in the cost of living, until now the cost of living in Canada is the highest of any country in the world. This is mainly due to national causes, both economic and sociological, which will be discussed in another article in the subsequent number of this journal. The labourer in the asbestos districts of Canada gets \$1.75 cents a day, and he cannot live on less. Similar labourers in the United States, we are credibly informed, receive \$1.50 a day.

In Russia they get from 30 to 40 cents a day. This is the one feature of the Canadian asbestos industry that deserves attention.

The prices that have been paid by the promoters of the Amalgamated Asbestos Corporation, Ltd., for the properties they have acquired are exorbitant. In order to meet the excessive fixed charges many expedients will require to be resorted to which will both retard the production of Canadian asbestos and encourage the production of other countries. If there should be a failure to meet these fixed charges, of course, the corporation goes into the hands of a receiver and possibly into liquidation. In this way large producing areas will become tied up in litigation, and the industry will be seriously injured. From every point of view it would be a sad mistake if any such fate should befall the asbestos industry of Canada.

## MINING OPERATIONS IN THE PROVINCE OF QUEBEC FOR THE YEAR 1908.

Abstract of the Official Report of Superintendent of Mines J. Obalski, M.E.

Notwithstanding the financial depression, the Province of Quebec did not fall off in mineral production during 1908. Instead of a falling off, a gain of nearly half a million dollars was made. The output of Quebec mines for 1907 was valued at \$5,019,932; for 1908 the corresponding figure is \$5,493,664.

### Iron.

The charcoal blast-furnaces of the Canada Iron Furnace Company, Ltd., and of John McDougall & Co., at Radnor and Drummondville respectively, have been purchased, and are being operated by the Canada Iron Corporation, Ltd. They are now units in an organization that extends over practically the length of Canada.

Local bog ore is used exclusively at Drummondville. At Radnor, as a mixer with bog ore, Ontario magnetite is utilized. Ore is also imported in small quantities from the United States.

The output of the furnaces is reported as follows:—

|                                                 |          |
|-------------------------------------------------|----------|
| ore charged, 15,493 short tons, worth.....      | \$60,020 |
| limestone charged, 2,887 short tons, worth....  | 1,337    |
| charcoal, 977,840 bushels of 20 lbs., worth.... | 85,738   |
| pig iron produced, 5,989 gross tons, worth....  | 171,286  |

The furnaces employ hot blast. Wood charcoal is manufactured on the spot in close kilns. Limestone is obtained from local sources.

Mr. Obalski makes his annual reference to the magnetic sands of the North Shore. "Experiments [in electric reduction] . . . have been made by the Federal Government, which attest the value of the process, but do not seem to demonstrate its industrial utility." Mr. Obalski is of opinion that the Grondal process may be commercially applicable.

### OCHRE.

The working of ochre at St. Malo and at Champlain, in the neighborhood of Three Rivers, has been continued. The operating concerns are the Canada Paint Company, Champlain Oxide Company, and S. W. McGill. The output for 1908 was 1,500 tons of crude ochre, worth \$4,500, and 1,346 tons of calcined and

ground ochre worth \$15,440. Sixty-one men are employed, and work is carried on for about seven months of the year.

### Chrome.

Only two companies produced chrome ore during 1908. These were the Dominion Chrome Company, at Little Lake St. Francis; and the Black Lake Chrome and Asbestos Company, at Black Lake. Both properties are under the same management. The concentration mills worked seven to ten months of the year.

The mills and mines of the American Chrome Company and of the Canadian Chrome Company were idle. These will probably resume work during this year.

A new company, D'Israeli Chrome Mines, Ltd., is exploiting a deposit in Lot V., 37, of Garthby. Prospecting has been done with encouraging results in Coleraine and Bolton.

The production of chrome in 1908, in long tons, was:—

|                            |            |                |
|----------------------------|------------|----------------|
| Second-class in lumps..... | 3,754 tons | worth \$38,740 |
| Concentrates . . . . .     | 3,000 " "  | 45,000         |
| Total . . . . .            | 6,754      | \$83,740       |

Seventy men were employed, and received wages totalling \$32,000. Work occupied only half the year.

### Copper.

The Eustis mine, at Capelton, was the only producer of copper. The Nichols Company's mines were shut down. The last-named company has been reorganized and has assumed a new name, the Albert Copper Company. The manufacture of sulphuric acid and other chemical products still continues.

Mr. Obalski advocates the establishment of a copper smelter at a central point in the Eastern Townships.

Copper ore shipped during 1908 amounted to 26,598 short tons, worth \$159,588. One hundred and twenty-two men were employed. They received \$50,030 in wages.

Lead, zinc, cobalt, silver, showed no further devel-

opment, although in the Township of Fabre prospecting results are encouraging.

### Gold.

At Lake Megantic the Marsboro Gold Fields Company continued to sink a shaft on Lots V., 1920, of Marston. The shaft is now 50 feet deep, and tests are being made. Definitive results have not been obtained as yet.

The Compton Gold Dredging Company proposes to dredge the gravel deposits in the valley of the Moe's River. Future results can only be guessed at.

J. OBALSKI.

Superintendent of Mines for the Province of Quebec.

### Asbestos.

Work was continued as usual in the asbestos districts.

At Thetford the Bell, King, Johnson, and Beaver mines were in regular operation. At the Beaver a new electric plant was erected. The Thetford Asbestos Exploration Company is preparing to work its property on Lot 28, Range VI., of Thetford. On Lot 16, Range IV., three miles from Robertson Station, the Robertson Asbestos Mining Company has done sufficient prospecting to encourage the erection of a mill.

On Lot 17, Range IV., some good prospects of excellent asbestos have been found. There is also a vein of chrome iron ore on this lot. There are many other partly developed prospects.

The American Asbestos Company, at Black Lake has changed its name to the British-Canadian Asbestos Company, Limited. The Union mine resumed work. This company does not ship its crude asbestos, but runs it all through the mill, and prepares a special quality of fibre.

Further notes of progress, discoveries, and additions to plants are given by Mr. Obalski. In his opinion, the asbestos industry gave good results during 1908.

The production for 1908 was as follows:—

|                          |                 |            |
|--------------------------|-----------------|------------|
| First-class crude .....  | 900 tons, worth | \$261.21   |
| Second-class crude ..... | 2,771 " "       | 438.30     |
| Fibre .....              | 13,911 " "      | 716.81     |
| Paper stock .....        | 47,574 " "      | 1,135.26   |
| <hr/>                    |                 |            |
| Total .....              | 65,157          | \$2,551.59 |
| Asbestic .....           | 24,011          | 34.66      |

Total value .....\$2,577.30

Four thousand two hundred and eighty-four workmen received \$1,066,774 in wages. It is noted that the increased output is chiefly paper stock.

Reference is made to the possibility of Russian Asbestos entering into strong competition with the Canadian article. In 1907, the production of the Ure region was 10,000 tons.

### Mica.

A bad market influenced this branch of the industry adversely. Only a few mines were worked. Among the principal shippers were Blackburn Brothers, H. I. Flynn, Kent Brothers, W. Argall, and the Calumet Mining Company. A large quantity remains on hand for this year's shipments. The total shipments of thumb-trimmed mica was 106 tons, worth \$95,311. One hundred and eighty-four men were employed. Work was intermittent. The amount expended in wages was \$47,724.

### Phosphate.

The Chemical and Fertilizer Company, of Buckingham, used 90 tons of phosphate. The Electric Reduction Company, of the same place, used tons. The whole amount, 175 tons, was worth \$1,610.

### Graphite.

Practically no graphite was mined during 1908.

### Magnesite.

In the year 1900 a considerable deposit of magnesite was found in the northern half of Lot 18, Range XI., Grenville Township, Argenteuil County. Very little attention was attached to it. Samples from this and other contiguous localities ranged from 74 per cent to 99.92 per cent, carbonate of magnesia.

In 1907, the lot mentioned above was acquired by Mr. T. J. Waters. A 200-ton test shipment was made and a quantity was calcined by the Canadian Carbonate Company, of Montreal.

The crude magnesite showed thus:—

|                             |                |
|-----------------------------|----------------|
| Carbonate of magnesia ..... | 84.50 per cent |
| Carbonate of lime .....     | 15.00 " "      |

The calcined product gave on analysis:—

|                |                |
|----------------|----------------|
| Magnesia ..... | 74.84 per cent |
| Lime .....     | 10.84 " "      |

DIAGRAM OF QUEBEC ASBESTOS PRODUCTION.

The mine lies 14 miles from the C. P. R. station, Calumet. Magnesite crops out over a length of from 400 to 500 feet, showing a width in one place of 60 feet. It has a snow-white crystalline form. A sample analyzed by Dr. Milton L. Hersey showed 86.60 per cent. carbonate of magnesia, and 11.43 per cent. carbonate of lime. The mineral can be used as a source of carbonic acid gas, and of magnesia. It also is easily worked for ornamental purposes. It has many other commercial uses, including the manufacture of

floor material. This is one of the very few large occurrences in Canada.

In Montreal, the Canadian Carbonate Company makes liquid carbonic acid out of European magnesite. Crude magnesite is worth about \$8 per ton. The calcined product fetches from \$30 to \$35 per ton. There is no duty on the entry of this product into the United States.

There appears to be the basis of a sound industry provided here.

Lists of operating companies, reports of official explorations in Labrador and Chebougaman complete Mr. Obalski's report.

### Statistics.

#### Summary Statement of the Production of the Mines of the Province of Quebec for the year 1908.

| NATURE OF MINERALS.<br>(Tons of 2000 lbs.) | Wages<br>paid. | Number<br>of<br>workmen | Quantities<br>shipped or<br>used | Gross<br>value |
|--------------------------------------------|----------------|-------------------------|----------------------------------|----------------|
| Bog iron ore .....                         | \$41,054       | 170                     | 11,628                           | \$30,957       |
| Calcined ochre .....                       | 12,596         | 61                      | 1,346                            | 15,440         |
| Raw ochre .....                            | .....          | ...                     | 1,500                            | 4,500          |
| Chrome iron .....                          | 32,000         | 70                      | 7,564                            | 83,740         |
| Copper ore .....                           | 50,030         | 122                     | 26,598                           | 159,588        |
| Asbestos .....                             | 1,006,774      | 2,484                   | 65,156                           | 2,551,596      |
| Trimmed mica .....                         | 47,724         | 184                     | 106                              | 95,311         |
| Phosphate of lime.....                     | .....          | ...                     | 175                              | 1,610          |
| Magnesite .....                            | .....          | ...                     | 65                               | 520            |
| Slates (squares) .....                     | 15,000         | 50                      | 4,335                            | 20,056         |
| Prepared graphite (lbs)                    | 6,920          | 22                      | 2,640                            | 165            |
| Flag-stone (sq. yds.)..                    | 2,400          | 50                      | 4,335                            | 3,600          |
| Cement (barrels) .....                     | 151,716        | 395                     | 801,695                          | 1,127,335      |
| Granite (cubic yds.)..                     | 238,761        | 653                     | 30,000                           | 250,000        |
| Lime (bushels) .....                       | 33,500         | 124                     | 556,000                          | 96,000         |
| Bricks .....                               | 300,000        | 1,462                   | 94,000,000                       | 525,00.        |
| Tiles and pottery .....                    | .....          | ...                     | .....                            | 270,000        |
| Lime stones (c. yds.)..                    | 155,882        | 515                     | 97,710                           | 223,580        |
| Totals .....                               | \$2,094,357    | 6,324                   |                                  | \$5,493,580    |

This table shows that the value of the mining products for 1908 was \$5,493,664, representing the value of the raw material or after having undergone the necessary preparation to make it merchantable.

This industry gave employment to 5,324 men, receiving \$2,094,357 in wages and working for periods of from 4 to 12 months.

According to the reports received, 7 men were killed and 5 seriously wounded in mining accidents.

### THE QUEBEC MINING LAW AS IT STANDS AT PRESENT.

1. The mines are reserved by the Crown on all the Crown lands and on the lands sold or patented for farming or other purposes after the 24th July, 1880, the owner of the surface having no right whatever thereon except to the damages. The land needed for mining may be expropriated by arbitration process before the Department of Mines.

2. Gold and silver are reserved by the Crown on all the lands, whatever may be the date of the patent.

3. Surface and underground may form one property, but can be separated in order to form two distinct properties, according to the wish of the owner.

4. The whole Province, surveyed or unsurveyed, is open for prospecting, except on territory already alienated for mining.

5. The staking out of a claim can be done only and personally by a prospector holding a miner's certificate. The cost of such certificate is \$10, good until the 31st December.

6. The staking out can be done on claims having an area varying from 40 acres to 200 acres in unsurveyed territory and on specified lots from one to two lots, forming a maximum of 200 acres. Within four months of the staking out, a mining license must be taken (a) on surveyed territory for the claim as staked out; (b) on surveyed territory for lots or fractions of lots, containing an area of from 1 to 200 acres.

7. In unsurveyed territory the claim must be rectangular in form, with north-south and east-west

orientation, and in surveyed territory the mining license will be bounded by lines parallel to the outlines of the lots, and the description must be furnished to the satisfaction of the Minister.

8. No evidence of discovery, assessment works or surveying is required in order to secure a mining license, but a fee of \$10, plus a rental of \$1 per acre per year, has to be paid in advance, and the same is renewable, so long as the necessary amount is paid to this Department.

10. The mine may be purchased upon payment of \$10 or \$20 an acre respectively within or outside of 20 miles in a straight line from a railroad in operation, the above being for a full claim or an entire 100-acre lot. The applicant must produce the proof of a mineral discovery, the concession has to be surveyed, and an amount of \$500 spent in mining work before the patent can be issued. On Crown land, the surface is sold with the mine, and on private land only the underground property, part of the surface being liable to expropriation, should same be necessary.

11. All applications and recording must be made through correspondence with the Department of Mines at Quebec until otherwise announced.

12. The prospecting license system has been abandoned, but the actual holders will keep the benefit of the same, and will have the right to renew them until the 1st of January, 1910.

### JAPAN'S STEEL, IRON, AND COAL.

The future that lies before Japan's mining and metallurgical industries is appreciated by very few outsiders. Geographically, Japan's position is most advantageous. Her climate is favourable. Her national progress in the production and utilization of minerals has been phenomenal.

In the period 1896-1900, inclusive, Japan produced 6,613,000 tons of coal. In 1907 her production amounted to 13,716,000 tons. During the first half of 1908 her estimated production was 7,000,000 tons. The average price of coal at the pit mouth is about \$2.25 per ton. During 1907 exports amounted to 2,922,000 tons, being about \$2.70 per ton; 141,000 tons were shipped to the Pacific Coast of the United States.

Most of the coal mines are on the seaboard. The seams range from 3 feet to 8 feet in thickness, and are easily worked; 60,000 miners are employed. The largest coal mine produces 1,100 tons daily. The yearly output per man employed is 240 tons. Coal-cutting machinery is now being introduced. Heretofore practically all the cutting has been done by hand.

The estimated available deposits of coal are put down at 1,200,000,000 tons.

In the southwest near the port of Sakai, rich deposits of iron ore have been found. Other deposits are known. Apparently none of these is yet worked. For the production of pig iron—42,919 tons in 1907—Chinese ore is imported. The Chinese ore is very rich. It is said to average 65 per cent. of iron. Domestic pig iron and steel sell at about \$24.50 and \$37 per ton respectively. Every effort is being made to increase production and to cheapen costs.

The Government steel works, at Yawata, employs 7,000 men. Three blast furnaces turn out a combined daily output of 450 tons. All branches of the steel industry are included in the establishment.

# LIST OF PERMISSIBLE EXPLOSIVES.

Tested prior to May 15, 1909.

As a part of the investigation of mine explosions authorized by Congress in May, 1908, it was decided by the Secretary of the Interior that a careful examination should be made of the various explosives used in mining operations, with a view to determining the extent to which the use of such explosives might be responsible for the occurrence of these disasters.

The preliminary investigation showed the necessity of subjecting to rigid tests all explosives intended for use in mines where either gas or dry inflammable dust is present in quantity or under conditions which are indicative of danger.

With this in view, a letter was sent by the Director of the United States Geological Survey on January 9, 1909, to the manufacturers of explosives in the United States, setting forth the conditions under which these explosives would be examined and the nature of the tests to which they would be subjected.

Inasmuch as the conditions and tests described in this letter were subsequently followed in testing the explosives given in the list below, they are here reproduced, as follows:—

(1) The manufacturer is to furnish 100 pounds of each explosive which he desires to have tested; he is to be responsible for the care, handling, and delivery of this material at the testing station on the United States arsenal grounds, Fortieth and Butler Streets, Pittsburg, Pa., at the time the explosive is to be tested; and he is to have a representative present during the tests, who will be responsible for the handling of the packages containing the explosives until they are opened for testing.

(2) No one is to be present at or to participate in these tests except the necessary government officers at the testing station, their assistants, and the representative of the manufacturer of the explosives to be tested.

(3) The tests will be made in the order of the receipt of the applications for them, provided the necessary quantity of the explosives is delivered at the plant by the time assigned, of which due notice will be given by the Geological Survey.

(4) Preference will be given to the testing of explosives that are now being manufactured and that are in that sense already on the market. No test will be made of any new explosive which is not now being manufactured and marketed, until all explosives now on the market that may be offered for testing have been tested.

(5) A list of the explosives which pass certain requirements satisfactorily will be furnished to the state mine inspectors, and will be made public in such further manner as may be considered desirable.

## Test Requirements for Explosives.

The tests will be made by the engineers of the United States Explosives Testing Station at Pittsburg, Pa., in gas and dust gallery No. 1. The charge of explosive to be fired in tests 1, 2, and 3 shall be equal in disruptive power to one-half pound (227 grams) of 40 per cent. nitroglycerin dynamite in its original wrapper, of the following formula:—

|                             |     |
|-----------------------------|-----|
| Nitroglycerin . . . . .     | 40  |
| Nitrate of sodium . . . . . | 44  |
| Wood pulp . . . . .         | 15  |
| Calcium carbonate . . . . . | 1   |
|                             | —   |
|                             | 100 |

Each charge shall be fired with an electric fuse of sufficient power to completely detonate or explode the charge, as recommended by the manufacturer. The explosive must be in such condition that the chemical and physical tests do not show any unfavorable results. The explosive in which the charge used is less than 100 grams (0.22 pound) will be weighed in tinfoil without the original wrapper.

The dust used in tests 2, 3, and 4 will be of the same degree of fineness and taken from one mine.\*

Test 1.—Ten shots with the charge as described above, in its original wrapper, shall be fired, each with 1 pound of clay tamping, at a gallery temperature of 77 degrees F., into a mixture of gas and air containing 8 per cent. of methane and ethane. An explosive will pass this test if all ten shots fail to ignite the mixture.

Test 2.—Ten shots with charge as previously noted, in its original wrapper, shall be fired, each with 1 pound of clay tamping at a gallery temperature of 77 degrees F., into a mixture of gas and air containing 4 per cent. of methane and ethane and 20 pounds of bituminous coal dust, 18 pounds of which is to be placed on shelves laterally arranged along the first 20 feet of the gallery, and 2 pounds to be placed near the inlet of the mixing system in such a manner that all or part of it will be suspended in the first division of the gallery. An explosive will pass this test if all ten shots fail to ignite the mixture.

Test 3.—Ten shots with charge as previously noted, in its original wrapper, shall be fired, each with 1 pound of clay tamping at a gallery temperature of 77 degrees F., into 40 pounds of bituminous coal dust, 20 pounds of which is to be distributed uniformly on a horse placed in front of the cannon and 20 pounds placed on side shelves in sections 4, 5, and 6. An explosive will pass this test if all ten shots fail to ignite the mixture.

Test 4.—A limit charge will be determined within 25 grams by firing charges in their original wrappers, untamped, at a gallery temperature of 77 degrees F., into a mixture of gas and air containing 4 per cent. of methane and ethane and 20 pounds of bituminous coal dust, to be arranged in the same manner as in test 2. This limit charge is to be repeated five times under the same conditions before being established.

Note.—At least 2 pounds of clay tamping will be used with slow-burning explosives.

In response to the above communication applications were received from 12 manufacturers for the testing of 29 explosives. Of these explosives, the 17 given in the following list have passed all the test requirements set forth, and will be termed permissible explosives.

Subject to the conditions named below, a permissible explosive is defined as an explosive which has passed gas and dust gallery tests Nos. 1, 2, and 3 as

\*With a view to obtaining a dust of uniform purity and inflammability.

described above, and of which in test No. 4  $1\frac{1}{2}$  pounds (680 grams) of the explosive has been fired into the mixture there described without causing an ignition.

#### Permissible Explosives tested prior to May 15, 1909.

 Provided:

1. That the explosive is in all respects similar to the sample submitted by the manufacturer for test.
2. That double-strength detonators are used of not less strength than 1 gram charge consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate (or its equivalent), except for the explosive "Masurite M. L. F." for which the detonator shall be of not less strength than  $1\frac{1}{2}$  grams charge.
3. That the explosive, if in a frozen condition, shall be thoroughly thawed in a safe and suitable manner before use.
4. That the amount used in practice does not exceed  $1\frac{1}{2}$  pounds (680 grams) properly tamped.

The above partial list includes the permissible explosives that have passed these tests prior to May 15, 1909. The announcement of the passing of like tests by other explosives will be made public immediately after the completion of the tests for such explosives.

A description of the method followed in making these and the many additional tests to which each explosive is subjected, together with the full data obtained in each case, will be published by the Survey at an early date.

#### Notes and Suggestions.

It may be wise to point out in this connection certain differences between the permissible explosives as a class and the black powders now so generally used in coal mining, as follows:—

(a) With equal quantities of each, the flame of the black powder is more than three times as long and has a duration three thousand to more than four thousand times that of one of the permissible explosives, also the rate of explosion is slower.

(b) The permissible explosives are one and one-fourth to one and three-fourths times as strong, and are said, if properly used, to do twice the work of black powder in bringing down coal; hence only half the quantity need be used.

(c) With 1 pound of a permissible explosive or 2 pounds of black powder, the quantity of noxious gases

given off from a shot averages approximately the same, the quantity from the black powder being less than from some of the permissible explosives and slightly greater than from others. The time elapsing after firing before the miner returns to the working face or fires another shot should not be less for permissible explosives than for black powder.

The use of permissible explosives should be considered as supplemental to and not as a substitute for other safety precautions in mines where gas or inflammable coal dust is present under conditions indicative of danger. As stated above, they should be used with strong detonators; and the charge used in practice should not exceed  $1\frac{1}{2}$  pounds, and in many cases need not exceed 1 pound.

Inasmuch as no explosive manufactured for use in mining is flameless, and as no such explosive is entirely safe under all the variable mining conditions, the use of the terms "flameless" and "safety" as applied to explosives is likely to be misunderstood, may endanger human life, and should be discouraged.

JOSEPH A. HOLMES,

Expert in Charge Technologic Branch.

Approved, May 18, 1909:

Geo. Otis Smith, Director.

#### ERNEST LEIGH FRALECK.

Ernest Leigh Fraleck died at Cobalt on Friday, May 27, 1909. Mr. Fraleck was recovering from an attack of typhoid fever. Death came unexpectedly.

E. L. Fraleck was born in Belleville, Ont., thirty-four years ago. His early education was acquired there. At an early age he entered Queen's University as an Arts student. After securing his B.A., he took a mining course in the Kingston School of Mining. Throughout his university career he was one of the outstanding figures in college politics. If I remember aright, "E. L." was never elected to office in the Alma Mater Society—an organization that governs the whole body of students—mainly because he was an out-and-out radical. But, whatever may have been his relation to college affairs generally, "E. L." had always a band of retainers who followed him implicitly.

I can recall, with absolute clearness, several occasions on which Fraleck spoke at Alma Mater gatherings. Frequently these meetings were stormy. Often a surprising amount of feeling was displayed by the speakers. I cannot remember one instance in which Fraleck either lost his head or made a false move. He was calm, forceful, and deliberate in his speech. It appeared to matter little to him if he lost an election. He always fought for some principle. Indeed he was essentially a fighter, and a constructive, clear-headed debater.

Fraleck's detached manner and his judicial attitude towards questions of the hour were apt to give the impression that his was a phlegmatic temperament. Such was by no means the case. Fraleck, as his professional work showed, was a man capable of profound and disinterested enthusiasm. His record in Cobalt is eloquent proof of this.

Because his strong character and vigorous mind were but beginning to be recognized more widely, and because his friends believe that a large sphere of usefulness lay before him, there is little necessity of detailing minutely the events in Fraleck's professional life. One paragraph will suffice.

After taking his mining course at the School of Mining, Kingston, he accepted a position as superintendent of a pyrite mine at Queensboro, North Hastings, Ont. While holding this post he followed and advised upon the development of other neighbouring properties. Later he joined the staff of the Ontario Bureau of Mines, and acquired an intimate knowledge of many of the mining districts of the Province. Early in the

ERNEST LEIGH FRALECK.

year 1907 he was appointed superintendent of the Cobalt Lake mine, Cobalt, Ont. This position he occupied until the day of his death.

Of Fraleek's efficiency as a mine manager there is no room for doubt. His work was neither erratic nor spectacular. It was carefully planned, thoroughly executed, and led always to definite results. His influence with the directors of his company was large. This influ-

ence he exercised wholesomely. The problems that confronted him in the development of the Cobalt Lake mine were intricate. The peculiar financial conditions under which the company had been organized did not make these problems easier. But Fraleek cheerfully met every difficulty, moulding and carrying out a wise policy of development, a policy that had absolutely no reference to the stock market.

In the last two years Fraleek was fast becoming a strong factor in Cobalt affairs. An earnest and whole-hearted citizen, he never spared himself in his efforts to rectify wrongs. On all matters of civic interest he was exceedingly well informed and constantly active.

But it was in his capacity as a member of the Canadian Mining Institute that Fraleek was best known. At the recent annual meeting he took a prominent part in the more important discussions. He was easily among the most effective speakers.

Recognition from his professional brethren came rapidly after his arrival in Cobalt. This year he was elected a member of the Council of the Canadian Mining Institute. The office of President of the Cobalt Mine Managers' Association he accepted and filled most efficiently. His advice and assistance were never denied to any worthy cause.

I think that it can be said of Fraleek that he was a sane, courageous, clear-headed Canadian. In any profession he would have won distinction. In the profession of mining engineering, a profession in which distinction is particularly hard to gain, Fraleek had already emerged from the rank and file. I am convinced that he would have accomplished great things had his life been spared.

Fraleek is dead. Many of his more intimate friends will never forget him, for he himself was a loyal and true friend. The Institute has reason to keep his memory green, for he laboured in season and out of season to aid and strengthen it.

To his bereaved family I believe a large measure of comfort must lie in the fact that Fraleek held and deserved the steadfast respect of his many acquaintances, and the abiding affection of his friends and associates.

J. C. MURRAY.

## MINERAL DEPOSITS OF THE SERPENTINE BELT OF SOUTHERN QUEBEC.

By John A. Dresser, McGill University, Montreal.

(Continued from last issue)

### IV. Chromite.

Chromic iron, valuable not for its iron but for its content of chromic oxide, occurs very generally in the peridotite and the serpentine of the Thetford, Black Lake and Danville type. The chief production is as yet from the Counties of Megantic and Wolfe, the former producing much the greater amount.

The placing of the industry on a substantial commercial basis has been largely due to the vigorous operations of the Black Lake Chrome and Asbestos Company, who are as yet the principal producers.

1. Production.—As early as 1861 samples of some tons' weight were shipped from Ham, in the County of Wolfe, to London and Glasgow, but no mining resulted, probably owing to the undeveloped state of the country, as the price of chromite was at that time four or five times higher than at present. In 1886 and 1887 another attempt was made to exploit the chromite ores of Quebec by Dr. James Reed, who shipped 100 tons from Wolfestown, Leeds and Thetford to Philadelphia. No further shipments seem to have been made until 1894, when operations were begun at several points, and

1,000 tons of ore were shipped. The returns of the Geological Survey record a production since that date valued at over \$600,000. The output of the last six years is as follows:—

| Production.          | Value.   |
|----------------------|----------|
| 1903—3,500 tons..... | \$51,121 |
| 1904—6,074 “.....    | 67,146   |
| 1905—8,528 “.....    | 104,565  |
| 1906—8,750 “.....    | 92,100   |
| 1907—7,196 “.....    | 72,091   |
| 1908—7,225 “.....    | 82,008   |

Canada, the total production of which is from this district, stands fourth among the countries of the world in the production of chromic iron, and furnishes about 10 per cent. of the world's output. The three leading countries are:—

|                     |             |
|---------------------|-------------|
| New Caledonia ..... | 51,000 tons |
| Russia .....        | 20,000 “    |
| Greece .....        | 15,000 “    |

of chromite are frequently scattered through all parts of these rocks. The general dissemination of ore throughout the rock, together with the highly altered and disturbed condition of the latter, would suggest that the ore bodies have been formed by concentration of ore from the surrounding rock, but detailed examination does not support this view.

The walls of the ore bodies are not usually well defined, and grains of chromite are quite as plentifully disseminated in the wall rock near the ore bodies as elsewhere. The deposits are irregular in shape, though they commonly have an approach to ellipsoidal outlines in a surface section, indicating that they are more or less lens-shaped. The longer axes lie parallel to the lines of fracture or cleavage in the country rock, that is, in a northeast and southwest direction, and so the form may be due to regional pressure which has been exerted on the ore bodies since they were formed. The majority of the ore bodies yet found are near, but rarely at, the contact of the serpentine, or peridotite

Fig. VI.—Photomicrograph of Chromite Ore.

Turkey, the United States and New South Wales produce smaller amounts. Turkey is reported to have large deposits of a good quality of ore, but the lack of railway or water transportation makes mining practically prohibitive at present prices.

A limited quantity of the Canadian ore has been used by the Electric Reduction Company of Buckingham, Quebec, in the manufacture of ferro-chrome. The remainder, except for occasional shipments to Europe, is shipped to the United States. It is there used for the manufacture of bichromates for use in dyeing textiles, tanning leather, for pigments in printing and painting; in making chrome steel; and lower grades for furnace linings.

2. Distribution of the Deposits.—The ore is found in the serpentine and peridotite, in some parts in large bodies of ore, in others, in mere nodules, while grains

with adjacent rocks, and none of importance are far from the contact. There appears to be no definite order in the distribution of the ore bodies, they being separated by bands of the country rock from a few inches to many feet in thickness.

3. Origin of the Ore Bodies.—These observations seem to indicate that these ores have originated by primary segregation from the peridotite magma, as was first suggested by Dr. F. D. Adams in a paper presented to the Province of Quebec Mining Association in 1894 (“On the Igneous Origin of Certain Ores”—Trans. Prov. Que. Mining Association, Montreal, 1894). A similar origin has since been established for the chromite ores of the Eastern United States by J. H. Pratt (Trans. A.I.M.E., 1899), while J. H. L. Vogt (Zeitschrift für Praktische Geologie, Oct., 1894) had pre-

only shown the chromite of Hestmandø, Norway, to be due to primary segregation.

4. Character of the Ore.—Chromic iron consists theoretically of an equal number of molecules of chromic and ferrous oxide, answering to the formula  $\text{FeO}$ ,  $\text{Cr}_2\text{O}_3$ , but ore of such purity has not been found in nature except in meteorites. Alumina and magnesia seem to be invariably present, replacing the  $\text{Cr}_2\text{O}_3$  and the  $\text{FeO}$  in varying proportions. Following are two analyses by T. Sterry Hunt of specimens regarded by him as typical of the Quebec deposits. (Geology of Canada, 1863, p. 479.) They are from the Township of Bolton, in the County of Brome, a locality which, although it has not yet produced ore on a commercial basis, seems likely to do so with proper development. Two analyses of chromite, one from Turkey, the other from New Caledonia, are also given for comparison:—

|                               |       |        |       |       |
|-------------------------------|-------|--------|-------|-------|
| $\text{Cr}_2\text{O}_3$ ..... | 45.90 | 49.75  | 51.70 | 55.70 |
| $\text{Al}_2\text{O}_3$ ..... | 3.20  | 11.30  | 14.10 | 16.20 |
| $\text{FeO}$ .....            | 35.38 | 21.28  | 14.20 | 16.20 |
| $\text{MgO}$ .....            | 15.03 | 18.13  | 14.30 | 9.80  |
|                               | 99.51 | 100.46 |       |       |

While the higher magnesia accompanies the lower percentage of iron, as would be expected in a simple replacement of the latter by the former, the higher alumina accompanies the higher chromic oxide. Hence the molecular combinations are more complex than might at first appear.

In discussing the ores of the Eastern United States, Mr. Pratt (op. cit.) has suggested that chromite is an isomorphous mixture of three distinct molecules,  $\text{FeO}$ ,  $\text{Cr}_2\text{O}_3$ ;  $\text{MgO}$ ,  $\text{Cr}_2\text{O}_3$ ; and  $\text{MgO}$ ,  $\text{Al}_2\text{O}_3$ . This hypothesis seems both necessary and sufficient to explain the variations in composition that are found in these ores.

In microscopic sections of ore from Black Lake the chromite is found to consist of two parts—a reddish-brown, translucent substance, and a black, opaque material (Fig. 6). Separations of these, which were effected by means of the Wetherill magnetic, and an hydraulic separator with ascending current, showed on analysis of the products a higher percentage of  $\text{Cr}_2\text{O}_3$  and  $\text{FeO}$  in the black portion than in the reddish part. Further investigation is being made by the writer on these, and on ores from other parts of the world.

The price of chromite is based on a standard of 50 per cent. chromic oxide, lower grades being penalized and those of higher quality being at a premium. Ores carrying less than 40 per cent. and as much as 10 per cent. are concentrated to 50 per cent., or a little higher. The first-class crude ores, or concentrates, rarely exceed 55 per cent., while theoretically pure chromite of the formula  $\text{FeO}$ ,  $\text{Cr}_2\text{O}_3$  should yield 68 per cent. The difference is evidently due not to defective ore dressing, but to the composition of the ore, which in Southern Quebec seems unlikely to be found to contain much above 55 per cent. of chromic oxide. As the analysis given above shows, ore from New Caledonia may have a somewhat higher percentage of  $\text{Cr}_2\text{O}_3$ , but is, as might be expected, lower in magnesia. While these features may make the New Caledonia ore more desirable for the bichromate industry, the higher magnesia probably favors the Quebec ores for use in the manufacture of alloys of steel.

#### V. Talc.

Talc and soapstone are practically undeveloped resources of the serpentine belt. Many portions of the intrusive rock, being originally rich in pyroxene, have

altered to steatite or soapstone, and frequently to a purer variety of talc. These are found principally in connection with the older serpentine of the Broughton series. On Lot 2, Craig's Road Range, of the Township of Ireland, in the County of Megantic, there is apparently a large deposit of talc of excellent quality. Unfortunately for the development of the property a little copper ore was found on it, and the prospectors' attention was turned from opening a promising talc deposit to selling a copper "mine." The property is eleven miles from the Quebec Central Railway at Black Lake.

Within one or two miles of the Quebec Central Railway, between Robertson and Broughton stations, there are several small hills of soapstone, some of which probably reach the quality of talc.

Several soapstone quarries have been opened at various times, chiefly for local use, in many parts of the serpentine belt, but no steady industry has as yet resulted.

From the Township of Potton, Brome County, a specimen of soapstone was taken which gave the following results in an analysis by T. Sterry Hunt:—

|                      | Potton | Pure Talc<br>(Theoretical Composition)                        |
|----------------------|--------|---------------------------------------------------------------|
| $\text{SiO}_2$ ..... | 59.60  | 62.8                                                          |
| $\text{MgO}$ .....   | 29.15  | 33.5                                                          |
| $\text{FeO}$ .....   | 4.50   | Usually contains a<br>little iron replacing<br>$\text{MgO}$ . |

A comparison with the composition of the theoretically pure talc, as cited here, indicates a comparatively high grade for the Potton deposits.

#### VI. Copper.

Copper occurs in three classes of deposits in the Eastern Townships of Quebec:—

1. In the limestones where they are invaded by dykes of igneous rock, as at Acton.
2. In a volcanic series—the porphyries and andesites of Capelon and Harvey Hill.
3. In the diabase of the serpentine series.

It is with this last only that this paper is concerned. These ores occur in pyrrhotite, while those of the Capelon and Harvey Hill series are in pyrite. In both cases the ore is chalcopyrite, and seems to have been introduced later than the pyrite or pyrrhotite bodies that contain them.

The largest of these bodies of copper have been found in the County of Brome, especially in the Townships of Potton and Bolton. The best known is the once famous Huntingdon mine in Lot 8, Range VIII of Bolton, which was vigorously operated between 1865 and 1873, while some work has been done more recently. During this period it is reported to have yielded from 200 to 400 tons per month of ore carrying between 7 and 10 per cent. of copper. The principal ore body lies in the diabase along its contact with Ordovician slates through which it is intruded. The width of the deposit mined is from eight to fourteen feet. Two miles north of the Huntingdon, on Lot 2, Range IX, of Bolton, is the Ives mine, which was worked for upwards of ten years. Similar ore bodies have been disclosed by smaller workings between these properties and to the north and the south of them. At the time of working the nearest railway was some twenty-four miles distant, but within the past three years the Orford Mountain Railway has been extended so as to pass in the immediate vicinity of these properties, all of which lie in the valley of the Missisquoi River.

Also in the same vicinity and within a little more than a mile from the railway is the Lake Memphremagog mine, on Lot 28, Range IX, of Potton. This property is on the west slope of Hog's Back Mountain, a diabase hill on the west shore of Lake Memphremagog. The ore is chalcopyrite and pyrrhotite, and probably ranges from 1 to 9 per cent. copper, with about 35 to 40 per cent. iron, and nearly the same amount of sulphur. After a period of disuse, this property is now being equipped with plant, and will soon again be worked. It is doubtless one of the largest ore bodies in the district.

A deposit of somewhat similar character is found to the northeast of the last in Garthby, near Lac Coulombre, in the County of Wolfe. The ore body here is so covered that its full extent could not be seen, but it is evidently of important size. In the interval of forty-five miles between this and the Lake Memphremagog deposits, several occurrences of similar ore are known. Probably the most important are in the Townships of Orford and Brompton, in the Counties of Sherbrooke and Richmond.

At a distance of one hundred miles northeast of Garthby, blocks of diabase carrying pyrrhotite and chalcopyrite were recently found in the Counties of Montmagny and L'Islet. Here the rocks of the serpentine belt occupy some twenty square miles of country, generally wooded, and in which probably no prospecting has ever been done. It is near the line of the projected extension of the Quebec Central Railway from St. George de Beauce to Temiscouata.

#### VII. Antimony.

Antimony is found in the diabase of the serpentine belt on Lot 28 of the first range of South Ham, Wolfe County. It was discovered here in 1863, and has been worked at two periods since that time, first by Mr. W. Russell, of Quebec, and later by the present owner, Dr. James Reed. No statistics of production are available. Two shafts have been sunk, one to a depth of one hundred feet, the bottom of which is reached by an adit some three hundred feet in length. At present no work is being done.

The ore consists of native antimony, valentite or oxide of antimony, and a little kermesite, the oxysulphide. It occurs in small veins, the largest about a foot wide, near the contact of diabase with sedimentary slates.

#### VIII. Nickel.

Nickel was mined for a time about 1882 on the sixth lot of Range XII., of Orford, in the County of Sherbrooke, by the well-known Orford Nickel Company, which was organized to operate the property. No records of these operations are available, but the quantity of ore was probably insufficient to make the work successful. Millerite, the sulphide of nickel, occurs here in calcite, but I have not been able to learn whether any other ore of nickel was obtained or not. The locality is now important chiefly for its excellent mineralogical specimens—millerite, ouvarovite and pyroxene—which are to be found in collections in many parts of the world.

#### Conclusion.

There is little detailed information available regarding the serpentine belt in the Shickshock Mountains. The explorations of Dr. A. P. Low and Dr. R. W. Ells, as well as of the earlier geologists of the Geological Survey of Canada, have shown that there is a large

development of these rocks. Considerable prospecting for asbestos has probably since been done, but thus far, without success. From such information as is available, the district seems likely to contain chromic iron at least, and prospecting for other minerals may yet be attended with success.

Platinum was found in the gravels of the Chaudiere valley many years ago by Sir William Logan. The natural habitat of that mineral is in the peridotites and serpentines, but it has not yet been traced to its source.

As these imperfect notes will have shown, the present knowledge of this complex series of rocks and the minerals they contain is very incomplete. Much remains to be learned and applied before the mineral resources of this area can be developed to the limit of their capacity. It is hoped that enough has been said to show that the serpentine belt is a factor of much present importance and of still greater prospective value to the commercial life of the Dominion.

#### FIELD WORK, GEOLOGICAL SURVEY, 1909.

The allotment of field parties, so far arranged for, is as follows:—

Mr. D. D. Cairnes will have a party in the Wheaton-Watson Rivers region in Southwestern Yukon.

Mr. R. G. McConnell will complete his examination of the geology and mineral resources of Texada Island.

Mr. F. H. McLaren will finish his topographic map of Texada Island.

Mr. W. W. Leach is engaged in mapping in the vicinity of Hazelton, Skeena River, and will examine in detail the coal area near Telkwa, discovered by him last season.

Mr. C. H. Clapp will continue his geological investigations on Vancouver Island.

Mr. R. H. Chapman will begin a topographical survey of Vancouver Island.

Mr. W. Sutton will report on the coal rocks of the east coast of Vancouver Island.

Mr. Charles Camsell will continue work in the Similkameen district, more particularly the Tulameer River district.

Mr. L. Reinecke will complete the topographical map of the Tulameen and begin a survey of the west fork of the Kettle River.

Mr. George Malloch will make a geological survey of the Fort George region on the Grand Trunk Pacific.

Mr. O. E. LeRoy will study the geology and ore deposits of the Slocan. He is now completing a geological map of the Sheep Creek mining camp.

Mr. W. H. Boyd will make a topographical map of the Slocan.

Mr. S. J. Schofield will be employed in mapping in the East Kootenay district.

Mr. John Macoun is continuing his natural history collecting in the west.

Mr. D. B. Dowling will investigate the coal lands of Alberta west of Edmonton.

Mr. W. McInnes will continue his geological investigations in the district north of Edmonton.

Mr. W. H. Collins is continuing his examination of the Gowganda district.

Mr. W. A. Johnston will resume his mapping of the Lake Simcoe region.

Mr. M. E. Wilson will be working north of Lake Temiskaming.

Mr. G. A. Young will continue his work in the Bathurst district, New Brunswick.

Mr. J. A. Dresser will continue his investigations on the rocks and economic minerals of the Eastern Townships.

Dr. R. W. Ells will complete his investigations of the oil shales of New Brunswick, and examine the shales of Nova Scotia and Gaspe.

Mr. E. R. Faribault will continue mapping the gold-bearing rocks of Nova Scotia.

Mr. H. Fletcher's field season will be spent on the coal formation of Cumberland County.

Mr. H. Ries, accompanied by Mr. Joseph Keele, will begin a study of the clays of the Dominion. The Maritime Provinces will be examined this season.

### PLATINUM CONSUMPTION.

England, United States, France, and Germany are the four chief consumers of platinum. The total annual consumption is about 366,000 ounces. One-third of this is scrap platinum, which, every year comes regularly into the market. Russian platinum production is between 200,000 and 300,000 ounces crude. Other producers are Sumatra and Borneo, Colombia, United States, and New South Wales. It is calculated that about 61 per cent. of the world consumption of crude platinum finds its way to the market secretly. This is being graded with a vengeance. To prevent this in

Russia it has been proposed that the export of crude platinum from Russia shall be absolutely prohibited. A special Commission is to fix every year in advance the quantities and the prices for the platinum to be sold abroad.

Nickel having come into extensive use in the kitchen, it is important to know what action food substances have on it, and how its compounds may affect a person eating food containing them. Late Russian experiments are reassuring on both points. Substances boiled in nickel vessels took up a small quantity of the metal—from 0.0002 with some foods to as much as 2 per cent. when the acid present is excessive; but a solution containing 4 per cent. of citric acid and 5 per cent. of common salt had only 0.144 per cent. of nickel after boiling three hours in a nickel vessel and then standing 11 hours in the same vessel. The physiological effects of nickel salts were slight, while there was no tendency to accumulate in the body after repeated doses. Nickel in quantities up to a quarter of a gram daily, in the form of lactate or butyrate, was given to two dogs for 202 days, with no result; and a dog that died after taking 9.7 grams (about a third of an ounce) in 40 days had no nickel in its body, its death having been due to some other cause. Doses as large as 1 to 2 grams daily were necessary to give any symptoms of poisoning.

## GOWGANDA MINING DIVISION, DISTRICT OF NIPISSING, ONTARIO.

Notes from Preliminary Report by W. H. Collins, Geological Survey of Canada.

### Location and Area.

The portion of the Montreal River region with which the present report deals lies in the extreme western part of the District of Nipissing, in the neighbourhood of N. Lat. 47.45, and about 85 miles north of the town of Sudbury. It includes an area of 350 square miles, most of which lies between the two large branches of the Montreal River, which empties into Lake Temiskaming on the west side.

### Means of Access.

In 1908 the most used route to the Montreal River district started from Latchford, a station on the Temiskaming and Northern Ontario Railway, 93 miles north of North Bay. From this village, situated on the Montreal River, a line of small steamers made daily trips up the river for 56 miles to Elk Lake. This up-river terminus was then a rapidly growing village. In the spring of 1907 it consisted of a single shack and a cluster of prospectors' tents; when seen in October, 1908, it had a population of over 200 people and all the conveniences of a village of that size, including a post-office with regular mail service, a mining recorder's office, lately removed from Latchford, general stores, hotels, etc.

From this point, which forms the headquarters and point of departure for Montreal River prospecting parties, a variety of routes lead westward. The Montreal River may be ascended to the Forks, where its two branches unite, but the stream is rapid, and, especially at high water, difficult of ascent, besides offering a very indirect route to the most frequented districts. The Bloom Lake route, a map of which accompanies the

Report of the Bureau of Mines, Ontario, 1907, was, during 1908, very commonly used. This route, nine miles in length and consisting of a chain of small lakes and portages, leads, from a point on the main river 11 miles above Elk Lake, directly west to the East branch. From the East branch many courses are open. Both East and West branches are easily navigable. Good portages exist at all these places, so that travel either up or down stream presents no difficulty. Numerous good canoe routes connect the two branches and Duncan and Pigeon Lakes, and allow of easy access to the country in the west.

### General Geology—Outline of Geological History.

Though the geology of the region presents considerable complexity of detail, the general historical facts are distinct and go to show that the whole complex of formations and systems is capable of separation into four major divisions widely different from one another. The mutual relationships of these divisions, a knowledge of which is essential to a thorough comprehension of the geology, are succinctly expressed by the accompanying diagram.

The oldest division, the Keewatin, comprises a complex association of metamorphosed rocks, principally eruptive, characterized by well-developed, secondary schistosity and prevalently dark colours. They dip at angles approaching 90 degrees, and range in texture from soft, fissile, chlorite schists to fine-grained gneisses or altered diabases. In the Montreal River district the Keewatin areas are not entirely visible, being overlain by other rocks, but they are thought to represent the bottoms of trough-like folds, produced by the upward

intrusion of igneous matter which now constitutes the Laurentian. The latter forms the second division, its origin being apparent from the foregoing statement. It is wholly igneous, consisting of granite and allied coarsely crystalline rocks essentially pale-coloured owing to their richness in quartz and feldspar. Gneissic structure has been developed in varying degrees, so that all gradations between granite and gneisses exist; but it never attains the perfection found in the Keewatin. Near their contacts with the Keewatin, the gneisses are apt to contain dark bands and ribbons of the latter so highly crystalline as to conceal their identity.

Wherever visible the surface of the Keewatin and Laurentian presents an irregular, deeply worn appearance, the result of extremely protracted exposure to erosive agencies. To the best of geological knowledge the same conditions hold where they lie buried under the Huronian, indicating that a great period of denudation separates the latter from the Archaean. The combined Keewatin and Laurentian, or Archaean system, is therefore to be conceived as forming at all points in the district an ancient denuded foundation or floor upon which rests the much younger Huronian system.

This third division is, in the Montreal River district,

Archaean and Huronian, but is ordinarily distinguishable by its unusual freshness, dark colour, and crystalline appearance. In certain cases, to be described subsequently, it may be confused with certain other diabases. Magmatic differentiative processes have evolved diabase types of very dissimilar appearance and mineralogical composition, of which a pink aplite occurring in dike form is the most extreme. Olivine diabase dikes are also present in the region, but in far less abundance.

Of little importance are the sands and gravels of glacial origin which lie thinly in the depressions and lower lands of the present plaiated surface.

#### Table of Formations.

The geological events may be briefly enumerated in ascending order as follows:—

Deposits of glacial debris and weathering products of present surface.

Erosive period with glaciation.

Diabase intrusions.

Huronian sedimentation.

Erosion period.

Laurentian intrusion.

Keewatin.

Diagram Illustrating Geological Relationships of Montreal River District.

wholly sedimentary and easily distinguished from the other rocks by its bedded structure and clastic nature. As it is the only sedimentary system represented, its members are not easily confused with any other, especially as their original structure is not obscured by metamorphic alteration. Locally this is not strictly true; in the vicinity of diabase intrusions they have been hardened and shattered so as to simulate the Keewatin, but the zones of alteration are narrow and readily identified by their gradation into adjacent areas of less altered types. At present the Huronian forms a discontinuous rock mantle over the Archaean, formerly more complete, but now worn through in places so as to expose portions of the crystalline basement.

The fourth division includes all eruptives known to be younger than the Huronian. Owing to the discontinuity of the latter it is not always easy to decide what rocks should be included in this group, for in some cases rather fresh-looking eruptives occur in the Keewatin which probably would also intrude the Huronian were it present; lacking the necessary information their chronological position can be only loosely fixed. By far the most extensive and important of the post-Huronian eruptives is the diabase with which the silver deposits are associated. This penetrates both

#### Economic Geology—Silver—Distribution.

With the knowledge acquired from exploitation of James Township, and other of the more recently discovered silver-cobalt camps, prospectors in the Montreal River district gave exclusive attention to the diabase formation, recognizing it to be closely connected with mineralizations of this kind. Some work was done in 1907, and more in the following season, with the result that on August 4 the first native silver discoveries were made, almost simultaneously and at short distances apart, by Messrs. Mann and Dobie, in the diabase just west of Gowganda Lake. The remarkable rich surface showings at once attracted the attention of the whole prospecting body in the Elk Lake country, and an activity began which, since the spreading of information to outside points, has developed into a "rush" of large dimensions.

The known silver bearing area is restricted as yet to about ten square miles lying between Gowganda Lake and the portage route from Elkhorn to Firt Lakes, and is commonly known as Gowganda. Extensive prospecting only commenced in September, about the close of the field season, so that only the earlier discoveries are known to the writer, and a knowledge of

the surface details could only be derived by examination of the few beginnings of patient and continued exploration by claim owners. The present account must accordingly be accepted as incomplete and by no means representing the present status of the Gowganda camp.

### Surface Indications.

Conditions in the region are such as to demand exploration of the closest and most intensive order, for the indications of mineralization are negative rather than positive in character. The Gowganda area was entirely forested at the beginning of 1908, and a carpet of moss and vegetable mould covered most of the rock surface. Glacial materials are also fairly abundant, and sometimes thick enough to render surface exploration arduous and expensive. Added to this the veins are eroded more deeply than the country rock, and are represented at the surface by crevices filled with soil, and thereby rendered inconspicuous. Were the country a flat one the difficulties in the way of successful prospecting would be very serious, but fortunately it is rugged, especially near the diabase. Steep ridges of this material are a regular topographical feature. The sides of these ridges are bare or readily exposed, and offer fine opportunities for examination. It is significant that the first silver discoveries were made in the sides of such rock walls.

ture, though not of mineralization, is found to obtain. The whole mineral association is not found in any one vein, nor are the relative proportions either of ore or gangue at all constant. The gangue minerals are quartz and calcite, always mutually arranged in a definite manner. The sides of the veins are composed of white quartz, which may form only an insignificant coating on the walls or may occupy nearly the whole space, but in all cases there remains a central cavity into which the pointed ends of quartz crystals project freely. At the surface this central portion is empty owing to weathering, but farther down it is filled by calcite. Veins with predominant quartz filling seem especially abundant in the Huronian adjacent to the diabase. The rich veins near Gowganda, so far as ascertainable, are poor in quartz.

Practically all of them carry chalcopyrite either as diffuse grains or in considerable amounts. Pyrite is equally abundant, but less constant. Galena is not uncommon. All these occur with the quartz; their presence in the calcite is not certainly known. Many of the veins show diffuse stains of reddish pink colour due to cobalt bloom, which, though not in itself of value, is important as a sign of the existence of smaltite, from which it is formed by oxidation. The minerals enumerated thus far are widespread, but economically insignificant; the silver-cobalt association is present in

Vertical Section Across Huron Ridge, North of Duncan Lake.

### Structure of Veins.

The deposits are in the form of well-defined veins occupying fissures in the diabase. The amount of surface work done in September was not enough to throw much light on the continuity of the veins, but a few had been traced for distances of 300 or 400 feet, and in one case across several contiguous mining claims, so that they may be said to occupy persistent fissures. They vary in width from 1 inch up to 20 inches. Little could be learned concerning their attitudes, except where they traverse hillsides; in such cases they are approximately vertical. It is not yet known whether any regularity exists in their arrangement, but some extend east and west, while others are north and south. The diabase shows no signs of extensive deformation, all geological evidence indicating that since its solidification its history has been uneventful, yet the cracks which the veins occupy appear too persistent to be the result of contraction by cooling. Besides the strong veins there are others of the gash type, but the latter are small, not very continuous, and poorly or not at all mineralized.

### Composition of Veins.

From comparison of veins at Gowganda, Duncan Lake, and Wapus Creek a general uniformity of structure,

some cases, however. Little opportunity existed in 1908 for favourable study of these minerals, so that only a list of those found at the surface can be given. There native silver, argentite, smaltite and cobalt bloom have been found, and a few feet down small lumps of native bismuth. Because they occur either in calcite or in loose decomposition materials filling the space which the calcite formerly occupied they are believed to be associated with that gangue. Infrequently gangue minerals are almost absent and the vein filled by massive ore.

(To be continued.)

Fraser & Chalmers recently gave an exhibition of a new form of tube mill. The new mill, while similar in most respects to the ordinary type, differs in one important feature. An eccentric motion is imparted by attaching the tube to the trunnions off centre. Greater activity is thus transmitted to the pebbles. The degree of eccentricity that will prove most efficient has yet to be determined.

# THE BULKLEY VALLEY AND VICINITY.

W. W. Leach.

(From Summary Report of the Geological Survey, 1908.)

During the past season the work undertaken in this district was chiefly in the upper parts of the valleys of the Morice and Zymoetz (Copper) rivers, though some time was spent in collecting sufficient geological and topographical information for the compilation of a new and enlarged edition of the map published last spring.

## Morice River District.

As the season was exceptionally late, it was found necessary to spend the earlier part of it in the lower levels; the valley of Clarks fork of the Morice being the first point to be visited. This stream rises with the south fork of the Telkwa, near Howson camp, in a wide, flat pass with an elevation of about 3,600 feet, thence its course is nearly due south for a distance of about 20 miles, when it unites with the main Morice River. Its chief tributaries are Starr Creek, Goldstream, Gabriel Creek, and a large unnamed creek coming in from the east a few miles below Gabriel Creek. From the mouth of Gabriel Creek down, the valley is wide, the hills on either side being comparatively low, with gentle slopes, while the grade of the stream itself is not great.

## Geology.

From the pass southward to about one-half mile below the mouth of Gabriel Creek the rocks met with consist of the volcanics of the Porphyrite group (underlying the coal-bearing beds), except for a short distance midway between Starr Creek and Goldstream, where the basal conglomerate of the coal series crops. It appears, however, that here the coal seams have been almost entirely eroded.

A short distance below Gabriel Creek the conglomerates again outcrop on the west side of the river, for a distance of at least eight miles, that being as far south as the valley was explored. Along this stretch the river follows pretty closely the strike of the rocks, near, but usually a little west of a synclinal axis. On the west side the dip of the strata is very low, conforming more or less to the slope of the hills. Practically the whole of the coal measures above the conglomerates has been lost by erosion. On the east side of the valley, however, the hills have a steeper slope; the dips are quite low and the synclinal axis is roughly parallel to, and some distance to the east of, the river bottom. Taking these facts into consideration, it was thought probable that an important coal basin might be found on the east side of the valley. Some days were spent, therefore, in carefully examining a number of small creeks on the east side, with the result that the conglomerates were found outcropping at from one to one and a half miles back from the river, at elevations varying from 400 to 600 feet above it, and with westerly dips. The conglomerate here appears to reach a much greater thickness than where observed elsewhere in this country. Two distinct beds were noted, the lower about 100 feet thick, and the upper probably 30 or 40; they are separated by about 50 feet of soft sandstone. On a small creek, about one mile below Gabriel Creek, and about one mile from the river, the coal-bearing shales were seen overlying the conglomerates. Two coal seams were here found, the lower one show-

ing 3 feet of coal, with no roof, while the upper one gave the following section:—

Clean coal, 12 inches.

Shale, 4 inches.

Coal, 3 feet 6 inches.

Later on in the season this point was again visited when it was found that during the interim Messrs. C. B. Clark and T. Howson had done considerable prospecting in the vicinity, and staked a number of coal claims. They had opened up what is undoubtedly the upper of the above-mentioned seams, at several points, showing it to be about ten feet thick and dipping to the west at thirty degrees. At none of these openings had they reached below the level of the surface waters, the coal in all cases being wet and decomposed, so that a sample taken at that time would hardly give a fair idea of the character of the coal. The seam, however, appeared to be quite regular, except at one point where a slight local disturbance was noted.

The following analysis from a sample taken under the conditions already mentioned. It can be confidently expected that the percentage of moisture, and probably of ash, will be materially reduced in a sample taken under more favourable circumstances:—

|                                       |       |
|---------------------------------------|-------|
| Moisture . . . . .                    | 10.81 |
| Volatile combustible matter . . . . . | 31.22 |
| Fixed carbon . . . . .                | 48.62 |
| Ash . . . . .                         | 9.35  |

Coke: non-coherent.

This area appears to be one of the largest in a district where the coal beds occur, as a rule, in small basins. Although the seams were opened up at one point only, still there is little doubt that this basin extends down to the forks of the Morice, and probably widens out below the place where the seams were stripped, at which point it is approximately three-quarters of a mile in width.

The general attitude of the strata is quite regular, the valley is wide, with an easy grade, and no serious engineering difficulties need be looked for in the construction of a branch line of railway down the Morice River, to connect with the main line of the Grand Trunk Pacific. There is a plentiful supply of timber in the valley for all future mining purposes.

## Goldstream Coal.

On Goldstream, to the north-west of this area and separated from it by a short distance only, another important coal basin is found, which was briefly described in last year's Summary. Since then, however, the locator, Mr. F. M. Dockrill, has opened up the seams at several new points, which proves this basin to be at least as large, and probably larger than it was estimated to be last year, viz., two by two and one-half miles.

The following results are from analyses made of samples taken this season:—

|                           | Moisture. | Vol. Comb. Matter. | Fixed Carbon. | Ash |
|---------------------------|-----------|--------------------|---------------|-----|
| (1) 8 ft. seam . . . . .  | 4.67      | 30.55              | 55.23         | 9.5 |
| (2) 6½ ft. seam . . . . . | 6.36      | 28.36              | 58.75         | 6.5 |
| (3) 3½ ft. seam . . . . . | 6.86      | 27.24              | 59.47         | 6.4 |

Coke: non-coherent in all cases.

All these samples were from surface coal, so that the percentage of moisture is in all probability higher than what will be found at greater depth.

#### Zymoetz River District.

Two other coal areas were examined rather hastily, both on that branch of the Zymoetz river which rises with Pine creek near the Hudson Bay mountains.

#### Glacier Creek Area.

The first of these is situated near the head of the river, which here occupies a wide, marshy valley. The coal-bearing beds were seen cropping in the bed of Glacier creek, a small stream rising in the Hudson Bay mountains and entering the Zymoetz from the east. The contact of the conglomerate and the underlying volcanics is at an elevation of from 500 to 600 feet above the valley, and at this point the strata are very highly flexed and otherwise disturbed, but have a general high westerly dips. Following down the creek from the contact, it was seen that everywhere the rocks have been severely folded and faulted till near the flat, where they become more regular, dipping under the valley to the best at about twenty degrees.

Some time was spent here in an endeavor to uncover a workable coal seam, but without success, although a number of small seams, from four to nine inches thick, were stripped. It would appear probable that the large seams of Goat creek are here split up into a number of small ones, though it is possible that larger ones do exist, whose outcrops are covered deeply with drift.

The coal here is very hard, with all the appearance of an anthracite, but the one sample taken showed by analysis such a high percentage of ash as to render it useless.

#### Coal Creek Area.

About eighteen miles from Glacier creek, down the Zymoetz river on its north-west bank, another area of the coal-bearing beds is met with. The best exposures are seen in a small stream from the north-east, locally known as Coal creek, which cuts the strike of the rocks at a wide angle. The beds here appear in the general form of a shallow syncline, with a general strike nearly north-west and south-east; but there are many minor undulations and the strata were seen to be faulted in a number of places. The width of the basin is probably about two miles, but its extent along the longer axis was not seen, though it is fairly certain that it does not go any great distance south-east of Coal creek. To the north-west the country has a gentle slope, is heavily drift-covered, and for a considerable distance there are no transverse valleys, so that it was found impossible to trace the coal-bearing beds farther in that direction, in the time available.

A number of coal claims have been staked here by Mr. J. Ashman, but so far little or no work has been done. Two small seams only were seen outcropping in the bed of Coal creek, about one and a half miles above its mouth. The lower of these showed 3 feet of clean coal, while the upper one was 1 foot 4 inches in thickness. Mr. Ashman has since informed me that he overlooked another seam that had been uncovered a short way from the bank of the creek and farther upstream, which was about 5 feet thick, with a small parting. The following analysis is from a sample from the lower or 3-foot seam:—

|                                       |       |
|---------------------------------------|-------|
| Moisture . . . . .                    | 5.45  |
| Volatile combustible matter . . . . . | 34.03 |
| Fixed carbon . . . . .                | 48.17 |
| Ash . . . . .                         | 12.35 |

Coke: partly fritted.

On the other coal properties, which have been described in previous reports, no new work has been undertaken during the past year, as all the owners of the lands in question are waiting for railroad construction, before going to the expense of further development.

#### Mineral Claims.

During the past season comparatively few prospectors were in the district, and new discoveries of importance were rare, while on the older and better known properties little work was attempted, except the annual assessment work required by statute.

On the Hudson Bay Mountains, more particularly on their western slopes, a number of claims are located and a large amount of prospecting has been done. The geological conditions here are very similar to those in the neighborhood of the copper claims of Howson and Scallon creeks, described in previous reports, the ore occurring in dikes from or near the edge of an eruptive area.

The northern part of the Hudson Bay Mountains is composed of rocks of the Porphyry group, chiefly volcanics (andesites, tuffs, etc.), but including, towards the top of the series, some sedimentary beds. These rocks have been very severely folded and crumpled; some splendid examples of folding on a large scale showing very plainly on the bare rocky walls of the higher peaks. Towards the southern end of this group of mountains, extending nearly down to the Telkwa River, there is a large intrusive area of granite-porphry, which has shattered, diked and altered the volcanics near its edge to a very large extent, thus affording channels for the ascent of mineral-bearing solutions.

Most of the chief showings are on a group of claims which are quite close together, and reached by a number of short branch trails from the main Aldermere trail.

#### Coronado Group.

On the Coronado group a considerable amount of work has been done, consisting of open-cuts, by means of which the vein can be traced for the length of two claims. The ore occurs in what appears to be a dike from the intrusive porphyry area, striking about north-east, with a nearly vertical dip, the strike conforming very closely to the slope of the mountain, here very steep. At the lowest opening a cut has been made 35 feet long and 12 feet deep at the face, exposing a lens of almost pure galena, varying from 14 inches in width at the face, to nothing, 12 feet back from it. Four and one-half tons of galena were shipped from the opening to a smelter, but the writer was unable to hear with what result. On the western or hanging wall there are about 3 feet of siliceous vein filling, carrying a little pyrites. A specimen of the clean galena gave by assay: gold \$1.20, and silver 62.63 oz., to the ton.

In the other cuts, farther up the mountain, the ore shows much less galena, but the mineralization is fairly heavy as a rule, one opening exposing about 4 feet of ore with no walls, the ore consisting of galena, blende, arsenical pyrites, pyrites, and lead carbonate in a quartzose gangue, but all much decomposed. A sample from this point assayed as follows: gold \$10; silver 3 oz., to the ton.

Near the eastern boundary of the Coronado, on the west bank of Sloan Creek, a similar and parallel ore body has recently been discovered. Here a lens of galena, nearly pure, but carrying a little blende and

chalcopyrite, has been uncovered, the greatest width of solid ore being 14 inches. This vein has been traced about 200 feet along the strike to the north-east; but as only the surface dirt has been removed in two or three small holes, the character of the ore could not be definitely seen. A specimen of the solid galena on assaying gave: gold \$4.40, silver 36.47 oz., to the ton.

### Victor Group.

The Victor group, consisting of the Standard, Victor, and Triumph claims, is situated west of the Coronado. The ore occurs in and along the east wall of a dike about 60 feet wide, striking about north-east, and dipping at 80 to 90 degrees southwest. It has been traced by means of open-cuts up the hill for a considerable distance. In the lowest cut about 3½ feet of ore is exposed, consisting of galena, blende and pyrites, irregularly and rather sparsely distributed in a gangue of altered dike rock and a little quartz. The ore appears to follow a line of faulting and shearing parallel to the walls of the dike. Fifty feet up the hill the ore has narrowed down to about 8 inches, with 3 inches of clean galena, a specimen from which assayed: gold, trace; silver, 43.33 oz., per ton.

Continuing up the hill, a number of superficial cuts show the dike rusty and decomposed, and varying from 12 to 60 feet wide, with mineralization strongest along the hanging wall. In one of these cuts about 2 feet of ore was seen, composed of blende, arsenical pyrites, with a little galena and chalcopyrite. At the highest opening up the mountain, about 2½ feet of ore is exposed, here highly decomposed, and consisting of stringers of galena, associated with much lead carbonates. A sample from this point gave the following results by assaying: gold, 20 cents; silver, 39.20 oz., per ton.

### Dominion and Newcastle Group.

The Dominion and Newcastle claims are located on the east bank of Sloan Creek, near its head. On this property a dike about 6 feet wide cuts the country rock, consisting of greenish and grayish andesites. The dike, with nearly vertical dip, has the usual northeast strike, and where opened up by means of a shaft and several open-cuts is very heavily mineralized, the chief constituents of the ore being blende, arsenopyrite, iron pyrites, a little chalcopyrite and a very little galena, in a gangue of altered dike rock and much quartz.

Two samples were taken here, the first consisting of the general run of the ore, while the second was from a band of almost pure arsenical pyrites; the results by assay are as follows: (1) gold \$5.80, silver 12.40 oz.; (2) gold \$3.60, silver 0.55 oz.

### Humming Bird Claim.

On the Humming Bird claim very little work has been done (by no means sufficient to prove the extent of mineralization) consisting of several small cuts, the chief one of which is about 15 feet wide, with neither wall uncovered. The rock is much decomposed, with a considerable quantity of a black, earthy material on the surface, which in the laboratory was proved to consist largely of pyrolusite. Beneath this decomposed material the ore is composed of blende, arsenical pyrites, galena, and iron pyrites in a felsitic gangue of altered dike rock, much shattered and brecciated; the mineralization being irregular and somewhat sparse. An assay of a sample from this cut gave the following result: gold 60 cents, silver 10.37 oz., per ton.

### Limestone.

As limestone suitable for smelting purposes has not before been noted from this district, the discovery of a bed of good quality may be of interest. This limestone occurs on the north side of the pass followed by the old trail from Moricetown to Hankins camp, on the Zymoetz River, and not far from the summit. As the only outcrop seen was in heavy timber, it was impossible to ascertain the thickness of the bed, but it would appear to be of good size. The following analysis was made in this office:—

|                                                                     |       |
|---------------------------------------------------------------------|-------|
| Insoluble matter .....                                              | 1.31  |
| Fe <sub>2</sub> O <sub>3</sub> Al <sub>2</sub> O <sub>3</sub> ..... | 1.30  |
| Ca CO <sub>3</sub> .....                                            | 92.41 |
| Mg CO <sub>3</sub> .....                                            | 3.63  |

As the writer was on the point of leaving Hazelton for Ottawa, a number of samples of ore were brought in from a reported discovery near that town. The ore consisted chiefly of stibnite, and gray copper. As the snow was then deep in the mountains, it was not possible to investigate this new find at that time.

### BOOK REVIEWS.

**Electro-Magnetic Ore Separation.** By C. Godfrey Gunther. 193 pages.. Illustrated, \$3 net. Hill Publishing Company, 505 Pearl Street, New York, 1909

Searchers after information concerning electro magnetic ore separation have had to be content with brief paragraphs or chapters in text-books on ore dressing. Mr. Gunther's volume is a compilation of the best available material, supplemented by data gathered by the author himself or submitted by mill managers and manufacturers. One object has been to include only facts which are of present commercial importance. Evidently selection and rejection have been necessary. Mr. Gunther informs us in his "Introduction" that in the United States alone over three hundred patents have been granted on magnetic separators. "The magnetic separator has been developed, in most instances for the exploitation of individual ore deposits, and the different types and modifications so produced might well form subject matter for a book. . . . In view of the above facts the broad practice of magnetic separation is incapable of monopoly, and its application is not determined by any one machine."

Another paragraph indicates Mr. Gunther's conception of the function of magnetic separation: "In its own field, which will be hereinafter outlined, magnetic separation is a useful adjunct to the specific gravity processes, but it is in no sense a competitor with these processes, except in the concentration of magnetite iron ores, and in this application is a success backed up by many years of profitable operation."

The book is divided into eight chapters. Into each of these we shall glance.

"Magnetism Applied to Ore Dressing" is the caption of the first chapter. Mr. Gunther outlines the whole study of magnetism. The application of magnetism to ore dressing is the phase of the subject with which mining men are concerned. This, then, is what Mr. Gunther proposes to present. Even in ore dressing magnetic separation has many refined applications that have not yet become commercial. Magnetic concentration has been applied principally to the treatment of magnetic iron ores, eliminating the gangue and partly separating the phosphorus and sulphur minerals. No

only magnetites, but limonite, chalcopyrite and other minerals are amenable to this treatment. The applications of magnetic separation are much more numerous and complex. After roasting, pyrite and marcasite become magnetic. Calcination transforms siderite and ankerite into magnetic compounds. Thus the separation of these minerals from zinc blende, a wasteful and inefficient process when attempted by wet methods, becomes possible by magnetism. There are other applications too numerous to mention, and, as the richer ores are becoming exhausted, the necessity of attacking lower grades gives more and more importance to magnetic methods.

The difference between specific gravity and magnetic-separation processes is that one utilizes differences in the specific gravities of the minerals to be separated, and the other utilizes the differences in their magnetic permeabilities.

Chapter II. gives the principles of magnetic separation, and preparation of the ore mixture to the magnetic field, attraction of the magnetic particles, removal of the attracted particles from the magnets, necessity of making a middling product, cleaning magnetite concentrate, treatment of fine material, are a few of the stages discussed in this chapter.

Chapter III. describes many types of separators for strongly magnetic minerals. The Grondal, Wetherill, Edison, Wenstrom, and other well-known machines are here illustrated.

In Chapter IV. are presented descriptions of separators for feebly magnetic minerals.

The concentration of magnetite ores is discussed in Chapter V. Results from the concentration of magnetite ores at representative mills, using different kinds of separators, are given. Briquetting of concentrates is touched upon. Several very useful flow sheets are included. This chapter is most instructive.

Chapter VI. deals with the separation of pyrite and blende; Chapter VII. with the separation of siderite from blende; Chapter VIII. with the separation of miscellaneous ores and minerals.

Throughout the book the aim of the author evidently has been to give practical point by taking instances and illustrations from actual practice. Whilst the book is frankly a compilation, the principles that form the basis of magnetic separation and concentration have not been neglected. The author's personal familiarity with his subject has enabled him to weld the various chapters into a coherent whole. His book is timely.

**The Mining Manual for 1908. By Walter R. Skinner.**

A record of information concerning mining companies, arranged in three sections, Australian, African, and Miscellaneous. Twenty-second year of publication. Price \$5 post free.

There are two manuals that every mining engineer should possess. Skinner's "Mining Manual" is one of them. The other, incidentally, is Stevens' "Copper Handbook."

It is impossible to do more than merely enumerate some of the leading features of Mr. Skinner's wonderfully complete volume. Monthly returns of gold outputs, over a period of years, are given for Australasia, Africa, India, and, in the Miscellaneous Section, for many other countries. In addition, lists of mining company directors, of mining company secretaries, and of

mining and consulting engineers and mine managers are appended.

Not only are the names of directors, amount of capitalization, conditions of flotation, etc., etc., specified for each company; but, so far as possible, the financial and physical conditions of each company's property are indicated.

The "Mining Manual" is a supremely useful work. It is a unique compendium of mining information, a directory, and a statistical and historical review.

## EXCHANGES.

**Mining and Scientific Press, May 22, 1909.**—The evolution of stamp-milling practice on the Rand has been saner, more gradual, and more successful than in the United States. This is the gist of an editorial in the current number of the Mining and Scientific Press. "For about ten years, stretching from 1890 to 1900, a sudden outburst of invention from the United States expended its fury in high-geight stamps. The increase from the old standard 750 to the 900 pounder was mainly promoted by cheaper transportation; the change could be made without altering the lines of mortars adapted to the lighter stamps; but when 1200-pound stamps were tried in the old mortars the output suffered, and costs were not reduced." To remedy this, "everything was done except to work out new mortar-patterns on the old model, adapted in details to the larger mass of pulp and to the altered wave-motion." Contrast this with the steady improvement of practice in South Africa. Here the mill superintendents, "with that spirit of conservatism which is so strong in British people, have been working out this problem according to the true principles of evolution, that of gradual change. . . . The result is that 9 tons of ore per stamp per diem is a common duty to-day on the Rand, obtained with 1,600-pound stamps." United States stamp-milling has not kept pace with the Rand. Nine-tenths of United States mills may be pronounced anachronisms. The cyanide process has advanced faster in the States than in South Africa. But the engineers on the Rand "are coming down the home-stretch at a rapid pace. They have perceived the need and value of co-operation and exchange of ideas as we have not."

**The Mining Journal, May 22, 1909.**—In a lengthy editorial the Mining Journal animadverts upon the disabilities under which the gold mining industry of Rhodesia suffers. The mining rights are vested in the British South Africa Company, which company administers the law. Recently, ordinances have been promulgated imposing a graduated tax upon the gross output of gold mines. The tax ranges according to the value of the gross output, from 2½ per cent. to 7½ per cent. The tax on base metal claims is lighter. But a property yielding ore from which any gold is extracted must be registered as a gold reef claim, and pay at the above rates for its total production. The Mining Journal quotes an instance in which the value of copper recovered is greater than that of the gold. The royalty in this case would amount to 20 per cent. of the mines' net profit. It is predicted by our contemporary that new enterprises will need exceeding attractive propositions to induce them to face these conditions.

**PERSONAL AND GENERAL.**

Mr. A. A. Cole, mining engineer to the T. & N. O., was in Toronto on June 7.

Hon. Mr. Templeman, Minister of Mines, is to visit Nova Scotia and New Brunswick some time in June.

Mr. F. G. Stevens, mining engineer, of Etzatlan, Jalisco, Mexico, was in Toronto on June 3rd and 4th. Mr. Stevens is a graduate of the Kingston School of Mining.

The Minister of Labour has appointed Mr. Charles Archibald, of Halifax, N.S., to the Conciliation Board that is arbitrating between the Cumberland Railway and Coal Company and its employees.

Mr. A. H. Brown, of Cobalt, Ont., who has made a specialty of cyaniding and milling, was in Toronto on May 31st. Mr. Brown, after spending a month in Gowganda, will return to Cobalt. His headquarters there will be the Coniagas mine.

**Correspondence.****Letter from Sir Henry Mill Pellatt.**

J. C. Murray, Esq.,

Canadian Mining Journal,

Toronto.

Dear Sir,—The death at Cobalt of Mr. E. L. Fraleck, Mining Engineer, after a short illness, came as a great shock not only to the management of the Cobalt Lake Mining Company, but also to his numerous friends throughout the Province.

Mr. Fraleck has been superintendent of the Cobalt Lake Mine since its organization in February, 1907. He always had the support of the directors of the company, as they had absolute confidence in his integrity and ability.

Mr. Fraleck's work was for many reasons one of the most difficult in the camp, but he was able to surmount all obstacles successfully.

The company will have great difficulty in securing an engineer to fill the position left vacant by the death of Mr. E. L. Fraleck.

HENRY M. PELLATT,

President Cobalt Lake Mining Company.

**LETTER FROM MR. MARRIOTT TO THE SECRETARY OF THE C. M. I.**

1 London Walls Bldgs.,

London, E.C., May 13, 1909

The Secretary, Canadian Mining Institute,

Rooms 3 and 4, Windsor Hotel, Montreal.

Dear Sir,—I beg to thank you for your favour of the 28th ult., containing a circular in connection with the prize offered to your Institute by Messrs. Frecheville, Commans and myself.

We note that, therein, you have further explained the scope of the papers eligible for the prize. Elimination of some sort is doubtless necessary for the guidance of the judges of the papers presented, but it appears to us that the wider the scope of the competition the more competitors will include and the more valuable will it be to the Institute. Our object in stipulating that the papers accepted shall include the most recent developments was to ensure that they should contain up-to-date matter which would be instructive to us, your guests of last year, and generally useful as containing the most recent information of Canada. If the contributors elect to put in still more work and to enlarge their papers to include history leading up to these recent developments, so much the better.

We trust that the prize will bring forth many competitors, and that it will produce several papers worthy of your country.

Yours faithfully,

(Signed) HUGH F. MARRIOTT.

**SPECIAL CORRESPONDENCE****NOVA SCOTIA.**

Glace Bay, June 4.—“Gluckauf” of the 15th May contains a summarized translation of articles which have appeared in the “Canadian Mining Journal” relating to the Dominion Coal Company's Rescue Station, and of a paper describing the use of breathing apparatus at the Sydney Mines Fire, which was recently read before the Institution of Mining Engineers in England. The article is very complete, and is from the pen of Bergassessor Grahn, a prominent German engineer, who has made a specialized study of mine rescue apparatus. An earlier issue of “Gluckauf” contained the first part of a description of Canadian coal and iron mines by Dipl. Ing. Kraynik, one of the gentlemen who visited Canada last summer on the occasion of the joint visit of the Iron and Steel Institute and the Institution of Mining Engineers. Herr Kraynik's article is extraordinarily complete, considering the brief stay he made in this country. “Gluckauf” is the leading mining periodical of Westphalia, and the consecutive appearance of two such complete descriptions relating to our Canadian mining industry is a proof of the useful nature of such visits as that just referred to, and also of the interest that our industries are creating in Europe.

The Board of Conciliation asked for by the U. M. W. A. at Sydney Mines has been granted by the Government, but the Board is not yet constituted. The Nova Scotia Steel Co. refused to appoint a representative, and the Government appointed Judge McGillivray. As at Glace Bay, the U. M. W. A. representative (and incidentally District U. M. W. A. President) failed to agree with the company's representative on a third arbitrator, and this duty will again devolve on the Government. Although this is the second occasion on which the U. M. W. A. President has been accepted by the Government as an “arbitrator” on a Board of Conciliation, it has not become apparent how such an interested person can “arbitrate” on the matters which the Conciliation Board will have placed before them.

At Springhill Mines the same procedure has been gone through as at Glace Bay and Sydney Mines. At this place Messrs. E. P. Paul and Charles Archibald could not agree on a third member and the Government has appointed Judge Longley as chairman.

For a society which has passed a resolution utterly condemning the Canada Industrial Disputes Act, root and branch, the U. M. W. A. nevertheless bids fair to become a record applicant for Conciliation Boards. Three in Nova Scotia, one in Alberta,

and further trouble brewing in British Columbia (where the U. M. W. A. is trying to call out the miners of Vancouver Island in a sympathetic strike with those in the Nicola district) is a fair number of disputes to have going on at once.

One of the pet shibboleths of the U. M. W. A. delegate in Canada is that his society is not here "to make trouble." The facts hardly tally with the expressed aims of this society.

May outputs were a decided improvement on those which have been obtained so far this year, although they were, of course, much less than those of last year. It is probable that although the production of coal will not reach such high figures as it did last year, yet the outputs will be more evenly sustained throughout the late summer and the autumn. There is a distinct optimism in Cape Breton just now, and so far this year more money has been spent on the erection of house property and improvements than has been the case for several years past.

The yearly examination for manager's underground, manager's and overman's certificates of competency has been held in Sydney, occupying three days, beginning June 1st. An unusually large number of persons presented themselves for examination. It is said that this is the last occasion on which the examination will be conducted under the present Board of Examiners, and that shortly the examination of aspirants for certificates will be placed under the direction of the Director of Technical Education.

The limitation of certificates of competency for mine officials by provincial enactments is a matter that we think should be remedied. There does not appear to be any good reason why a man who is considered competent to undertake the direction of a mine in Nova Scotia should not be qualified to act as an official in Alberta or British Columbia. We do not suggest that the provincial governments should not issue such certificates in each province, but it should not be necessary for a fully qualified mining engineer to undergo an examination in every province in which he may happen to be engaged. Some day, no doubt, the Federal Government at Ottawa may see fit to issue a certificate that will cover the whole Dominion. Such a certificate would, of course, require to be surrounded with conditions and safeguards which would prevent any abuse thereof.

#### ONTARIO.

**Cobalt.**—The pipe for the Hydraulic Company is being distributed around the camp, and it is now stated that air will be ready for delivery about the first of August. It is very doubtful, however, if this will be possible, considering the amount of work still to be done. More machine drills have been ordered for the cutting out of the air chamber above the tunnel, it being found that the hammer drills did not give good satisfaction. There are nine miles of 20-inch pipe to be laid between Ragged Chutes and the town, and from the end of this line a 12-inch loop will encircle the town. In addition there will be branch lines out by the Colonial and Kerr Lake Mines. The pressure in the main will be about 110 pounds to the square inch, and the air is to be delivered at the mine at a pressure of 100 pounds. Large users will buy air by meter, while the smaller consumers will pay according to a sliding scale. The terms are as follows:—

For large consumers buying by the meter, twenty-five cents per thousand cubic feet of air at 100 pounds pressure. The following rates per drill per ten-hour shift have been fixed upon for the smaller users:—

|                                  |        |
|----------------------------------|--------|
| 1 drill, per 10-hour shift.....  | \$5 00 |
| 2 drills, per 10-hour shift..... | 4 00   |
| 3 drills, per 10-hour shift..... | 3 50   |
| 4 drills, per 10-hour shift..... | 3 13   |
| 5 drills, per 10-hour shift..... | 2 80   |

In addition, those mines not using more than five or six drills will have to pay for their own connections with the main

line. Figuring on the basis of twenty-five cents per thousand feet, this gives the cost per drill for one shift approximately \$2.50, that is, supposing the drill to be working all the time. In reality, however, the machine is actually drilling little more than half the time, which gives a net cost per shift of about \$1.25. This leaves a very wide margin in favor of the consumption by meter, and it is altogether probable that before anything definite is done in the matter, some concerted action will be taken by the mines to force the Hydraulic Company to give a more uniform rate to all purchasers.

The transmission line for electrical power from Fountain Falls is expected to be completed about July first. The rates are stated to be as follows:—Under 25 h.p., 3 cents per kilowatt hour; between 25 and 50 h.p., 2 cents per kilowatt hour; between 50 and 100 h.p., 1 3-4 cents per kilowatt hour; between 100 and 200 h.p., 1 1-2 cents per kilowatt hour; between 200 and 300 h.p., 1 4-10 cents per kilowatt hour; between 300 and 400 h.p., 1 3-10 cents per kilowatt hour; between 400 and 500 h.p., 1 2-10 cents per kilowatt hour; over 500 h.p., 1 cent per kilowatt hour. In addition to this there will be a service charge of \$1.00 per month per horsepower on the rated capacity of the meters. A discount, with a maximum of 13 per cent., will be allowed, the same to be based upon the load factor.

Progress is being made on the erection of the new concentrator for the Colonial Mine. The framework is being erected and the stamp batteries are already set up. A five by sixteen foot tube mill to be direct driven from a motor has also been ordered. The mill will not turn over until the electric power company have their power ready for distribution, and it is expected that the mill will be completed by then.

The largest float, silver nugget ever seen in this district was found on the property of the Gem Mining Company, situated near the southeast part of Giroux Lake. It measures 5 feet 7 inches in length, is 2 feet 4 inches wide, and about sixteen inches thick. The weight is over a ton. The company will shortly start trenching on the property.

Following the discovery of ore in the Beaver Mine, the company has decided to rebuild their plant, which was burned down some time ago. The new vein is being drifted on, and the values are as good or better than when it was first discovered.

There is a great rush up the Montreal River from Latchford, eight hundred men having made the trip up on the boats in six days, while a great number had to remain behind, failing to get accommodation. Over thirty cars of freight billed up the river are tied up at Latchford owing to the inability of the navigation company to handle them in the present condition of the river.

The opening of navigation has caused increased activity to be displayed in the district of South Lorraine. Among the principal properties in this section are the Keeley, Wettlaufer, Haileybury Silver, Montrose, South Lorraine Development, Harris, Kelley-Jowsey-Wood, and the Great Northern. The majority of these properties are controlled by Buffalo capitalists. The Kelley mine is installing a large plant consisting of a 150-h.p. gas producer and a 12-drill compressor. The Wettlaufer is also installing a plant consisting of two 60-h.p. boilers and a five-drill compressor, which it is expected will be running in about a month's time. The South Lorraine district was located in the fall of 1907, but work was not started until the following spring, and although up to date the amount of ore shipped has been small further development is expected to bring the district well to the front.

Work will be stopped in the drifts of the Station Grounds Mine until the air from the Hydraulic Company is ready for delivery. Previous to this the company had been purchasing air from the Cobalt Lake. In the meantime prospecting will be carried on with a diamond drill.

At the Farah Mine the second discovery within two weeks was made on May 24th, when a new vein carrying silver was

discovered. The shaft, which is being sunk about the middle of the property, has reached a depth of 100 feet, but will be continued deeper before a crosscut is started.

Recently one of the easterly workings of the Nipissing went through the Keewatin formation into the diabase. As it is generally considered that the diabase was the agent that brought up the valuable minerals this discovery will probably have an important bearing on the future development of the mines. More extensive exploration of the Keewatin may be looked for in the future, and the probability is that a good deal of diamond drilling will be done to determine the thickness of this series.

The Crown Reserve now has workings about 60 feet deep in the Keewatin and the values are reported to be fully as good as in the overlying rock. One of the Nipissing veins has also at the present time excellent values in the Keewatin.

On May 28th another new strike was made at the King Edward Mine, on the No. 5 vein. The ore shoot was encountered while drifting west at the 80-foot level, and it is about four inches in width, consisting of calcite and native silver.

One of the finest specimens of silver ore ever produced in Cobalt was taken recently from the Crown Reserve. The piece measured 18 x 22 x 16 inches and is valued at over \$2,000. It has been sent to the Geological Survey at Ottawa and will form a part of their collection.

The Keystone Cobalt Mines, Limited, owning property in South Lorraine, has started work at surface prospecting. This property was purchased last fall by Bradford, Pa., parties.

There are two diamond drills operating at the Foster Mine. One is at the 210-foot level and the hole is now under Glen Lake. The formation is Keewatin and it is desired to ascertain whether or not the Huronian slates come in, as was found to be the case underlying the diabase at the Big Pete. The other drill is working on the surface. Two machine drills are also being worked underground.

The report of the Otisse-Currie shows that up to date the sum of \$31,000 has been spent on the development work, plant, supplies, etc. It is proposed to sink another shaft in the north-east corner of the property on a vein found in that section, and the different shafts will be connected underground. The present shaft is also to be sunk to a depth of 150 feet, at which level a crosscut will be run across the property, after which sinking will be continued to a depth of 250 feet. It is proposed to continue the ore shipments during the summer months by hauling to Elk Lake and from there shipping by boat to Latchford.

At the Big Pete mine of the Cobalt Central about four hundred feet of work has been done in the Huronian slates underlying the diabase and the results are very satisfactory, some of the finest showings in the mine being found at this depth. The shaft which down 260 feet, will be continued another 50 or 75 feet as soon as possible. The diamond drill has shown that all over the property the Huronian slates underlie the diabase, the knowledge of which will be of great value to the Big Pete and the surrounding mines in deciding upon their future development. During the month of May the Cobalt Central Mill treated 750 tons of low grade ore for the Kerr Lake.

The Donaldson claims at Bloom Lake have been sold to New York capitalists. Mr. J. Hermon, formerly of the Progress Mine, will take charge of the property.

Last fall Mr. A. M. Bilsky and his associates in the Jacobs Exploration Company purchased 168 acres adjoining the Nipissing and Chambers Ferland on the north and the Temiscaming and Hudson Bay to the north-east. To operate this property a company, known as the Cable Silver Mines Company, Limited, was formed. This is a close corporation. A considerable force of men are now engaged in trenching and some good indications have been uncovered. As soon as the air from the Hydraulic Company is on the market preparations will be made to sink.

The Silver Nugget is a property that adjoins the Lawson and the University on the south, and it takes in a part of the eastern portion of Giroux Lake, in which there is located an island of considerable size. On this island a shaft was sunk to a depth of 120 feet on a 4-inch vein of calcite, carrying iron, copper and galena, and from the bottom 150 feet of drifting was accomplished. At the time this work was being carried on compressed air was leased from the University Mine, but subsequently when operations commenced on the Lawson the lease for this air expired and now new arrangements will have to be made to secure similar power. In the meantime, while these arrangements are being made, two diamond drills will operate, one to be placed on the island and the other on the mainland, and the holes will be bored to tap the veins at depths of 200 feet from the surface. The indication which will be tested on the mainland is a decomposed calcite vein about nine inches wide. A great amount of interest has been shown in this as it has been traced on the surface from the southern extremity of the famous Lawson vein. This property also belongs to the Jacobs Exploration Company.

A short time ago a number of engineers working for the Provincial Government commenced a resurvey of the 20-acre lots of the Gillies Limit, which have been put up for disposal by private tender. Those best posted say that sale will not create nearly the amount of interest formerly expected. Had it taken place two years ago the Government would have been ahead to the extent of millions of dollars. Lack of interest is due largely to the fact that the Provincial Mine, which is surrounded by the lots to be sold, is so far a flat failure. About \$100,000 has been expended on the mine, while the returns from ore shipments will hardly net a tenth of that amount.

A new record for ore shipments in the Cobalt camp was made in the month of May when 43 cars of high grade, 2 cars of medium, and 35 cars of low grade were shipped. This makes 80 cars of ore, having a total weight of 5,017,433 pounds.

## BRITISH COLUMBIA.

**Rossland.**—The sempiternal optimism of the Rossland mining and business man is once again to the fore and in this district it is felt that there are busy and prosperous days in store for the mines of this camp in the very near future. Well may we feel a little hopeful as we look over the situation at the Centre Star group of the Consolidated Co., working conditions at the mines of the Le Roi 2, Limited, activity in the South Belt, the growing industry of the big smelter and refinery at Trail, a few miles down the hill, and the assurance that a big plan of development from the 1,650 to the 2,650 levels will be begun at the Le Roi mine as soon as a few financial arrangements have been completed by that indefatigable managing director of the Company, Mr. Anthony J. McMillan.

The production of the Consolidated Company's smelter at Trail for the month of April was as follows: This work treated 35,490 tons of gold, copper, silver and lead ore, extracting 410 tons of copper matte and 2,264 tons of lead bullion, which contained in gold, \$214,835; silver, \$101,891; copper, \$44,232; and lead, \$146,110, or a total metallic production of \$507,068. Of this product the refinery turned out metals to the value of \$246,371. From June 30th, 1908, to April 30th of this year the Trail smelting works produced precious and useful metals to the value of \$4,088,940, about \$2,096,461 of which must be credited to work at the up-to-date refinery in operation there. If this rate of production is maintained until June 30th, 1909, this year's product will be worth nearly \$1,800,000 more than that for the last fiscal year. This certainly shows progress.

The gross production of the Le Roi 2, Limited, for April was \$67,770 for 2,200 tons of gold-copper ore, or something over \$30.80 per ton, making the net profits of the company for that

month between \$35,000 and \$40,000; this spells a magic word to the stockholder—dividends.

The president of the Blue Bird Mining Co., visited the camp a few days ago and looked over the property. Drifting on the ledge is in progress and ore is being got out for shipment. The ore at 40 feet deep in the shaft, where 60 foot of drifting has been done, maintains a width of one to three feet and looks persistent. The reef on which this property is located runs through the south belt and in a westerly direction over the hills to the Southeastern Boundary district; there are mines working at different points along its course and it is probable that this vein will become well known in local mining annals before many years have passed. The present lessees of the Blue Bird may have to give up their lease when it expires, which will be in about five months, as Mr. Carter is trying to work out a plan whereby the Company will take over and operate the property itself after the expiration of the present lease. On this same lead the Hattie Brown and Richmond are also working at present. Shaft work is being done on both properties with a view to developing the vein.

**Boundary.**—The Boundary ore production for the week ending May 29th (18,377 tons) exceeded that of the preceding week by 4,637 tons, and it is more than likely that next week will see an even greater increase as during the past week the third augmented furnace at the Grand Forks smelter of the Granby Consolidated was put into operation and the next few days will see No. 4 blown in and work resumed at the Gold Drop outlet. The Granby and Snowshoe are the only steady shippers in this district just now, with an occasional shipment from the Golden Eagle and Sally. It is to be hoped that the B. C. Copper Co. will resume work early, now that the Alberta coal miners' strike has been settled, and that the Dominion Copper Mines will be on the shipping list again in the impending future, as present rumor would have it. Of course, this last looks doubtful, there are so many factors in the case, but if some party gets a cinch on the property at the sale in Vancouver, May 28th, then it is likely that work will be started, for it costs too much to let a big mining and smelting property like this lie idle. The mines have been kept unwatered and the machinery in good repair so that it would be no gigantic task to start work.

The Snowshoe Mine is shipping 10,000 tons of ore per month regularly to Trail smelter, where it is valuable as a flux, and is used with the Rossland and Slocan ores. All ore is at present being taken from above the tunnel level in the Snowshoe, there being an abundance for all present requirements, and the mine will not be unwatered below the level of the adit for the present. The report of the Snowshoe Mining Co. shows that that company is making a good profit on its lease of the Mine to the Consolidated Co. and is steadily paying off some of its old debts at the bank.

The Canadian Pacific Railway Co. has commenced surveying the 12-mile branch line that will run south from Hartford to Wellington and Central camps and to the Lone Star Mine in Washington, which the B. C. Copper Co. controls. This will give the Copper Co. railway facilities for its No. 7 mine in Central and its Athelstan Fr. and Jack Pot claims in Wellington. The company has 200,000 tons of ore ready for shipment from the No. 7 and about 80,000 tons from Wellington. This would seem to predict heavy operations for the B. C. Copper Co. during the latter months of this year.

This work of driving the big tunnel at Greenwood is now going along smoothly and the adit has been advanced nearly a hundred feet into the hill already. The operators, the Greenwood-Phoenix Tramway Co., are contemplating the installation of an eight-foot tunnelling machine of the Swiss-Chandler type. This will cost in the neighborhood of \$60,000 but in the end would prove very economical, under good working conditions.

The shaft on the Golden Zone, near Hedley, is now down about 115 feet and at that depth the vein has been proved up ten feet wide and assays of \$20.67, \$45.47 and as high as \$82.68 per ton in gold and \$1.10 silver have been obtained. The five-stamp mill will shortly be put into operation. This mill is equipped with ten-stamp equipment and the other five stamps will be added when required.

**Slocan—East Kootenay.**—The much jumbled affairs of the Sullivan Group Mining Co., with mines at Kimberley and smelter at Marysville, are again on the carpet and owing to the backwardness of some 35 per cent. of the shareholders, the bondholders are going to take things into their own hands and proceed with reorganization. The latest plan set forth is to issue 1st preferred stock bearing 7 per cent. annual dividend, to cover the amount of the bonded indebtedness, with interest, amounting to over \$400,000. Second preferred stock, bearing same dividend rate, will be issued to cover the other outstanding liabilities, which are over \$60,000. This stock, however, will differ from the 1st preferred in that it will be subject to recall by the company at par. Common stock will be issued to the amount of the 1st preferred stock and this will be divided among the bondholders, as they are, of course, to pay all costs of reorganization, etc. The bonds are at present held by the Federal Mining & Smelting Co. in which the Guggenheims are heavily interested. The Sullivan Company's smelter is said to be worth about \$500,000 and there are about 150,000 tons of ore blocked out in the mine which will average 15 per cent. lead, 6 1-2 ounces silver and a percentage of zinc—and "there's the rub." It is the zinc, probably combined with a little poor management, that has got the company into its present fix. The ore is difficult to treat now that the zinc has come in more plentifully at depth and this problem the new company will have to solve to put the concern on a first-class basis of operation.

The manager and part owner of the rich Westmount claim has just returned from the east where he has made arrangements for a plan of development to be done on that property. The work will be begun at once, on No. 3 tunnel. It will be remembered that Mr. Griffith drove his 1000-ft. prospect tunnel alone in the rugged hills, working sometimes for months at a stretch without hearing the sound of a friend's voice; such pertinacity certainly deserves the reward that Mr. Griffith reaped when he broke into the long-coveted ledge, from which he shipped nearly 400 tons of high-grade silver lead ore last year.

The Dunsmuir interests, whose name is synonymous with big coal mines in this Province, will begin work on the Noble Five group at Sandon in the near future. This is a promising property which local miners have tried in vain to lease lately, knowing its prospective value. Part of the ore is of a concentrating character and there is an old concentrator on the ground that will be fixed up.

A gold strike has been made on the Cascade river near Devil Creek, about three miles from Bankhead, Alta. Samples of the sand submitted for analysis to Dr. Taylor of Bankhead, show coarse-grained gold in good quantities.

The McGillivray Creek Coal & Coke Co., near Coleman, have just about completed arrangements for the installation of 10,000 feet of electric railway from the mines to the track of the C.P.R., also for a new steam power plant and tippie. The stock of the company is heavily held in Spokane, Wash., and B. E. Sharp of that city is secretary and treasurer. The company owns 3,000 acres of promising coal land is forging ahead in good shape.

It is stated that work will be resumed on the Mohican group of the Poplar Creek gold mines in a short time. There is a very good body of concentrating ore in the tunnel on this property. Nine tons have been shipped as a test, but as railway facilities have been lacking it has been difficult to get ore out to the smelter.

May 29th, 1909.

# GENERAL MINING NEWS.

## NOVA SCOTIA.

**Springhill Mines.**—One May 28th Tillman White was fatally injured in No. 2 shaft. He was caught by the trip. White was a native of Springhill.

**Mabou.**—Judge MacGillivray has filed his decision in the matter of the lien for labourers' wages, materials, etc., against the colliery of the Mabou Coal and Railway Company. Two hundred and seventeen claims were filed and proved. Valid liens to the amount of \$7,897.51 were proved. The total amount of claims allowed, including personal judgments, was \$9,908.02.

**Sydney.**—The Board of Examiners, presided over by Mr. R. D. Anderson, Deputy Commission of Mines, began its session on June 1st. One hundred candidates are taking the mining examinations.

## QUEBEC.

**Sherbrooke.**—The British-Canadian Asbestos Company, Limited, has made many changes in its mill during the past winter. There are now six cyclone pulverizers installed. Mr. E. Slade, the manager, superintended the alterations.

At the Dominion Asbestos Co.'s plant of cyclone pulverizers have been replaced by rolls.

The Suffield copper mine, six miles south of Sherbrooke, is being developed under the management of Capt. Wm. Jenkin.

## ONTARIO.

**Cobalt.**—Cobalt's tonnage for the first five months of 1909 is about 12,400 tons, or practically 5,000 tons in excess of the shipments for the first five months of 1908. Crown Reserve is one of the mines that made a record in May. It sent out eight cars of high-grade ore and two cars of fair ore.

Of the eighty-one cars shipped from the camp during May 43 were high-grade.

**Cobalt.**—The Beaver mine is shortly to make a shipment of high-grade ore.

During the month of May the silver production of the La Rose will be the result of heavy shipments of high-grade ore. The month's output amounted to 525 tons, of which 297 tons were of high-grade ore, averaging between 2,500 and 3,000 ounces of silver to the ton. On May 31 La Rose sent out 43 tons of high-grade and two tons were made up of metallies, almost bullion.

This was the last month in the company's year; a clean-up was possibly made. However, on June 1 the company had 62 tons of high-grade sacked and three cars of second-grade ready for shipment. A car of high-grade was also ready to be crushed.

Two hundred and seventy-five men are now employed by La Rose Consolidated Co. Trenching will soon be started on undeveloped acreages owned by the company, so that the number of men will be materially increased.

**Port Arthur.**—The rush for the Sturgeon Lake gold district gold district will begin in the first week of June. Navigation will then be open. A new 100-foot stern paddle steamer has been placed on the lake by the New Ontario Transportation Co. This will connect with the C. P. R.

## ALBERTA.

**Coleman.**—At the meeting of the Canadian Mining Institute, held at Coleman, Alta., on the 25th inst., W. A. Davidson, M.E., occupied the chair. Several papers were presented. One of these was by M. J. Powell, mine manager of the International Company's mine, of which a description was given, together with the particulars of the system of ventilation and of haulage; another was by E. Jacobs, on "Notes on Coal Mining, etc., in Alberta," this being a summary of recently published official reports; and a third, by F. W. Gray, of Sydney, B.C., on "Oxygen Breathing Apparatus in Coal Mines."

## BRITISH COLUMBIA.

**Hedley.**—The Nickel Plate mine has been bonded by the Daly estate to M. K. Rogers for a large sum. The Nickel Plate is equipped with a 40-stamp mill, which has been in operation for ten years.

**Rossland.**—Mr. G. O. Buchanan, lead bounty commissioner, has received the cheques for the lead bounty up to March 31st. The mines entitled to the bounty are as follows: Alpha, American Boy, Arlington (Erie), Arlington (Slocan), Peterborough Trading Co., Banker, Bismarck, Black Diamond, Bluebell, Canadian Group, Cook, Early Bird, Elkhorn, Emerald, Flint, Frances, Hot Punch, Giant (Golden), Jessie, Bluebird, Last Chance, Gallagher, Maestro, Maggie, Niel, Pontiac, Queen Dominion, Rambler-Cariboo, Reco, Rio, Richmond-Eureka, Ruth, Sally, Silver Bell, Silver Sovereign, Ruby Silver, Spokane Standard, Sunset, Vancouver, Wellington, Westmount, Whitewater Deep, Hewitt, Wakefield, St. Eugene, Ymir, Blue Bird (Rossland).

**Trail.**—The value of the B. C. Smelter product of the Consolidated Mining and Smelting Company for April is reported to be \$507,068. For the past ten months it amounts to \$4,083,940. More than half of this came from the refinery. Improvements and enlargements being carried on have not interfered with the output.

**Rossland.**—Le Roi mine, it is persistently rumoured, is to start again very shortly.

**Rossland.**—The largest copper furnace in Canada has been blown in by the Consolidated Mining and Smelting Company at Trail. The dimensions of this furnace are 42 inches by 25 feet. The company has now four large copper furnaces, with a capacity of 1,800 tons of ore per day. Mechanical feeders are being installed on the large lead furnace, which now produces more lead bullion than any other lead furnace on the continent.

**Vancouver.**—On May 28th bids aggregating \$155,000 were made for the Dominion Copper Company's properties. These bids were not sufficient to equal the reserve bids fixed by the court, and the sale was postponed until June 4. The property was offered in two parcels. The Hayden Committee, represented by Samuel Untermeyer, was the only bidder. The Lincoln Committee made no bids whatever.

**Victoria.**—Working under instructions from the Federal Department of Mines, Mr. R. H. Chapman is about to commence a topographic survey of Vancouver Island.

## MINING NEWS OF THE WORLD.

### GREAT BRITAIN.

The directors of the Cape Copper Company, Limited, have announced an interim dividend of 1s. 6d. per share, free of income tax, on the cumulative preference and ordinary shares.

With an eye upon the present strained relations between miners and operators, the Admiralty officials are particularly active in placing orders for steam coal in the Welsh coalfields. In the last week of May, vessels were charged at Cardiff for the carriage of 50,000 tons of coal for home depots.

The Scottish Coal Miners' Federation refused to go to arbitration over the men's demand for a daily minimum wage of 6s. This has practically dissolved the Scottish Coal Conciliation Board. Nine-tenths of the coalmasters are losing money. Thus both coalmasters and miners are preparing for a crisis. The miners number 80,000 men. They have an accumulated fund of £70,000.

### GERMANY.

All the employees of the West Bohemian Mining Association in the district of Mies, Bohemia, have gone out on strike. The men demand a fixed minimum wage.

### SOUTH AFRICA.

The long-continued dispute between the Government and the mining companies in regard to their respective rights in the Bewaarplaatsen and water rights areas has been settled. The claim areas will be worked by the companies, the Government taking 40 per cent. of the net profits.

A great extension of deep level movement is taking place. Hundreds of claims are being taken up at points far removed from the outcrop of the main reef.

The successful flotation of the Carolina Asbestos Development Company has been followed by the purchase, for development and

flotation, of several adjoining properties in which the Lydenburg Estates, Limited, and other owners are interested.

The total output of gold from Rhodesia for the month of April was 52,906 ounces, valued at £222,700; as against 48,030 ounces, valued at £202,157 in the previous month. The output of other minerals during April was: Silver, 21,495 oz.; lead, 82 tons; copper, 4 tons; chrome ore, 1,748 tons; asbestos, 28 tons.

### AUSTRALIA.

What is claimed to be the largest body of silver-lead ore yet found in South Australia was discovered recently about 23 miles south of the Olary railway station.

The number of men employed last year in the gold mining industry in Western Australia was 16,500. Money expended in wages, stores, and freights, amounts to about \$26,000,000. Dividends paid, totalled \$7,350,000.

### UNITED STATES.

The National Mining & Smelting Co., Deming, New Mexico, is to treble the capacity of its plant. Latterly the mine has been closed.

The Butte Central and Boston Copper Corporation is to resume work in the Opir Mine. The corporation has been reorganized and has adopted a new name—the Butte Central Copper Co. A concentrator is to be erected.

Rawhide, Nevada, is soon to have ample mills of its own. The King Heizner mill will be completed early in July. Other mills are projected.

The Miami Copper Co., Globe, Arizona, is erecting the first unit of its overground capacity. The power-house, bins, mill, etc., will be built to a capacity of 1,500 tons of ore daily.

The Interstate Mining Co., Wallace, Idaho, has raised over \$100,000 wherewith to equip its property. The proposed development includes driving a 3,000-ft. tunnel.

## COMPANY NOTES.

The Dominion Copper Co. has been purchased by the bondholders' committee, of which Charles Hayden, of Hayden, Stone & Co., is chairman.

The shareholders of the Temiskaming & Hudson Bay Mining Company have empowered the directors to raise the capitalization from \$25,000 to \$3,500,000. It is reckoned that on that basis one share of the old company will be worth 400 of the new, and that on that basis it will be distributed.

The 400,000 shares left in the treasury after the distribution of the stock on the new basis will be used for the erection of a concentrator at the plant on the most northerly lot of the company where the mine is at present, and the development of the south end of the property. The directorate believe that there are excellent possibilities at the end near the Silver Queen, and very little has been done there.

Two years ago a shaft was sunk near the line of the Temiskaming & Hudson Bay and the Silver Queen, and mining was in operation there before the big vein was found on the other end of the holdings.

### TILT COVE COPPER.

The report of the Tilt Cove Copper Co., Ltd., for 1908, was presented at the meeting on May 25th, and states that the profit and loss account shows a credit balance of £9,107. The Cape Copper Company's Tilt Cove establishment audited accounts for the year show that the mines made a gross profit of £26,627, which, after charging the account with the rent (representing the interest on the debentures), prospecting costs, management, etc., and after adding the balance brought forward, with interest, etc., leaves a net profit of £21,323, with £53,256 to be carried forward to next year's accounts. The balance of profit thus remaining has been dealt with as follows: £10,662 has been retained by the Cape Copper Co. and £10,662 has been received by this company as its moiety of profit, as provided for in the agreement with the Cape Copper Company. Although a profit of £21,323 is shown on the establishment account, that result includes the items of £36 released from the amount of profit spent on buildings and machinery and £944 from the amount retained for working capital. This company's share of the £944, together with the £36, has been deducted from the capital expenditure on the one side of the balance-sheet and from the

reserve for depreciation on the other. Out of the available profit of £12,581 an interim dividend of 1s. 3d. per share was paid on 2nd December, 1908, £1,665 has been paid in income tax, and the committee now recommend a final dividend of 6d. per share, making a total distribution of 1s. 9d. per share, of 4% per cent. for the year, leaving £3, 127 to be carried forward.

### INTERNATIONAL NICKEL CO.

The International Nickel Co. and constituent companies in America, of which the Canadian Copper Co. at Sudbury is one of the chief producers, reports for the fiscal year ended March 31, 1909, as follows:—

|                                       |             |                |
|---------------------------------------|-------------|----------------|
| Earnings . . . . .                    | \$2,162,694 | Dec. \$272,259 |
| Administration expenses, etc. . . . . | 139,393     | Dec. 10,191    |
| Net income . . . . .                  | \$2,023,401 | Inc. \$262,068 |
| Deductions, depreciation . . . . .    | 267,102     | Inc. 51,127    |
| Mineral exhaustion . . . . .          | 100,205     | Inc. 5,853     |
| Bonds sinking fund . . . . .          | 177,000     | Inc. 8,750     |
| Interest bonded debt . . . . .        | 473,500     | Dec. 8,550     |
| Total deduct. . . . .                 | \$1,017,807 | Inc. \$57,180  |

|                                   |             |                |
|-----------------------------------|-------------|----------------|
| Balance . . . . .                 | \$1,005,494 | Dec. \$319,248 |
| Preferred dividend . . . . .      | 534,734     |                |
| Surplus . . . . .                 | \$470,760   | Dec. \$319,248 |
| Previous surplus . . . . .        | 2,216 799   | Inc. 461,182   |
| Total surplus . . . . .           | \$2,687,559 | Inc. \$141,934 |
| Reserves . . . . .                | 230,599     | Dec. 98,227    |
| Profit and loss surplus . . . . . | \$2,456,960 | Inc. \$240,161 |

President A. Monell, in his remarks to the stockholders, says that all construction work has now been completed, with the exception of repair shop and foundry, at Copper Cliff. The report continues:—

"The last fiscal year followed as an aftermath of the panic of 1907, and brought with it all of the depressing conditions incident to such a state of affairs. Many of our customers worked their stocks up very close. As our sales are largely to steel manufacturers, they are susceptible to the influences which govern that industry."

The balance sheet as of March 31 shows cash on hand amounting to \$436,441; total current assets, \$4,426,574, and total current liabilities \$1,915,574.

At the annual meeting, held yesterday in New York, the retiring directors were re-elected. W. H. Bronson was chosen to fill the vacancy caused by the death of Joseph Wharton.

## STATISTICS AND RETURNS.

### DOMINION COAL FIVE MONTHS' OUTPUT.

The Dominion Coal Company's output in May was 316,000 tons, against 335,000 last May. The total is behind that of a year ago.

|                    | 1909.     | 1908.     | 1907.     |
|--------------------|-----------|-----------|-----------|
| January . . . . .  | 195,971   | 312,358   | 231,606   |
| February . . . . . | 206,970   | 283,358   | 225,716   |
| March . . . . .    | 251,585   | 344,129   | 310,220   |
| April . . . . .    | 294,934   | 303,249   | 316,384   |
| May . . . . .      | 306,888   | 335,829   | 327,269   |
| Total . . . . .    | 1,263,458 | 1,578,923 | 1,411,195 |

The May output of the Nova Scotia Steel and Coal Co. was as follows:—

Collieries, Sydney No. 1, 20,731 tons; Sydney No. 2, 6,593; Sydney No. 3, 16,619; Sydney No. 4, 5,322; Sydney No. 5, 11,266. Total, 60,531 tons.

Iron, steel and coke: Pig iron, 5,780 tons; steel, 5,486; coke, 1,000.

This compares very favourably with the May output last year, which was 53,588. The gain was made notwithstanding that No. 3 was idle for seven days, while a new condensing plant as being installed. No. 5 also lost three days while a change was made to a new bankhead and new picking belts and screens were put in.

### COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt Camp:—

|                            | May 22.     |
|----------------------------|-------------|
|                            | Ore in lbs. |
| Coniagas . . . . .         | 64,300      |
| Crown Reserve . . . . .    | 126,400     |
| Kerr Lake . . . . .        | 203,760     |
| King Edward . . . . .      | 43,130      |
| La Rose . . . . .          | 291,400     |
| McKinley-Darragh . . . . . | 50,670      |

|                                    |         |
|------------------------------------|---------|
| Nipissing . . . . .                | 453,860 |
| Peterson Lake . . . . .            | 67,580  |
| Right of Way . . . . .             | 249,130 |
| Temiskaming & Hudson Bay . . . . . | 60,000  |

Ore shipments to May 22, 1909, from Jan. 1, are: 22,388,023 pounds, or 11,194 tons. Total shipments for week ending May 22 are 1,610,220 pounds, or 805 tons.

|                            | May 29.     |
|----------------------------|-------------|
|                            | Ore in lbs. |
| La Rose . . . . .          | 195,680     |
| Crown Reserve . . . . .    | 161,680     |
| Nipissing . . . . .        | 194,146     |
| O'Brien . . . . .          | 128,190     |
| Temiskaming . . . . .      | 59,000      |
| Nancy Helen . . . . .      | 43,400      |
| Trethewey . . . . .        | 65,300      |
| Buffalo . . . . .          | 43,574      |
| McKinley-Darragh . . . . . | 46,780      |
| Right of Way . . . . .     | 81,228      |
| Chambers-Ferland . . . . . | 60,000      |

1,078,978

Total shipment for year, 23,467,001 pounds, or 11,733 tons.

### COBALT ORE SHIPMENTS.

Following are the weekly shipments from the Cobalt camp, and those from Jan. 1, 1909, to date:—

|                            | Since Jan. 1. |
|----------------------------|---------------|
|                            | June 5.       |
| Buffalo . . . . .          | 471,204       |
| Coniagas . . . . .         | 780,930       |
| Crown Reserve . . . . .    | 2,390,728     |
| Cobalt Central . . . . .   | 308,165       |
| Chambers-Ferland . . . . . | 580,440       |
| City of Cobalt . . . . .   | 747,522       |
| Kerr Lake . . . . .        | 871,528       |
| King Edward . . . . .      | 141,160       |

|                            |         |           |
|----------------------------|---------|-----------|
| La Rose .....              | 239,128 | 5,875,926 |
| McKinley-Darragh .....     | 59,460  | 746,560   |
| Nipissing .....            | 325,715 | 5,324,109 |
| Nova Scotia .....          |         | 480,810   |
| Nancy Helen .....          |         | 480,810   |
| Nancy Helen .....          |         | 83,400    |
| Peterson Lake .....        |         | 200,540   |
| O'Brien .....              |         | 909,976   |
| Right of Way .....         |         | 1,516,030 |

| Temiskaming .....          | 60,000  | 1,292,260 |
| Trethewey .....            | 127,000 | 1,037,928 |
| T. & H. B. ....            |         | 794,800   |
| Muggley Consolidated ..... |         | 72,900    |

Ore shipments to May 29, 1909, from Jan. 1, are 24,774,572 pounds, or 12,387 tons. Total shipments for week ending June 5 are 1,307,571 pounds, or 653 tons.

#### BRITISH COLUMBIA ORE SHIPMENTS.

The output at the mines for the week ending May 22 has been slightly under the average. The following are the details:

##### Boundary.

|                   | Week.  | Year.   |
|-------------------|--------|---------|
| Granby .....      | 17,495 | 378,049 |
| Snowshoe .....    | 1,410  | 44,342  |
| Other mines ..... |        | 140,871 |
| Total .....       | 18,905 | 563,262 |

##### Rossland.

|                             |       |        |
|-----------------------------|-------|--------|
| Centre Star .....           | 3,302 | 62,343 |
| Le Roi No. 2 .....          | 617   | 12,251 |
| Le Roi No. 2 (milled) ..... | 260   | 5,040  |
| Other mines .....           |       | 9,409  |
| Total .....                 | 4,179 | 89,043 |

##### Slocan-Kootenay.

|                                |       |        |
|--------------------------------|-------|--------|
| Queen (milled) .....           | 420   | 8,190  |
| Granite-Poorman (milled) ..... | 250   | 4,850  |
| Whitewater Deep (milled) ..... | 700   | 13,800 |
| Kootenay Belle (milled) .....  | 70    | 1,370  |
| Second Relief (milled) .....   | 145   | 2,830  |
| Nugget (milled) .....          | 110   | 2,150  |
| Bluebell (milled) .....        | 900   | 17,600 |
| Lucky Jim .....                | 154   | 488    |
| Whitewater Deep .....          | 150   | 1,324  |
| Bluebell .....                 | 139   | 1,985  |
| Silver King .....              | 159   | 1,657  |
| Van Roi .....                  | 61    | 141    |
| Richmond-Eureka .....          | 100   | 1,441  |
| St. Eugene .....               | 494   | 7,305  |
| Yankee Girl .....              | 36    | 339    |
| Other mines .....              |       | 5,722  |
| Total .....                    | 3,888 | 71,192 |

The total shipments for the week were 26,972 tons, and for the year to date, 723,497 tons.

#### SMELTER RECEIPTS.

|                                   | Week.  | Year.   |
|-----------------------------------|--------|---------|
| Granby, Grand Forks .....         | 17,495 | 378,319 |
| Consolidated, Trail .....         | 6,352  | 138,657 |
| B. C. Copper Co., Greenwood ..... |        | 140,505 |
| Le Roi, Northport .....           |        | 12,761  |
| Total .....                       | 23,847 | 670,242 |

#### BRITISH COLUMBIA ORE SHIPMENTS.

For the week ending May 29 the following ore shipments are reported:—

##### Boundary.

|                   | Week.  | Year.   |
|-------------------|--------|---------|
| Granby .....      | 18,377 | 396,426 |
| Snowshoe .....    | 2,895  | 47,237  |
| Other mines ..... |        | 140,871 |
| Total .....       | 21,272 | 584,534 |

##### Rossland.

|                             |       |        |
|-----------------------------|-------|--------|
| Centre Star .....           | 3,559 | 65,902 |
| Le Roi No. 2 .....          | 261   | 12,512 |
| Le Roi No. 2 (milled) ..... | 260   | 5,300  |
| Other mines .....           |       | 9,409  |
| Total .....                 | 4,080 | 93,123 |

##### Slocan-Kootenay.

|                                |       |        |
|--------------------------------|-------|--------|
| Queen (milled) .....           | 420   | 8,610  |

The total shipments for the week were 29,353 tons, and for the year to date 752,732 tons.

#### SMELTER RECEIPTS.

|                               | Week.  | Year.   |
|-------------------------------|--------|---------|
| Granby, Grand Forks .....     | 18,377 | 396,696 |
| Consolidated, Trail .....     | 7,849  | 146,616 |
| Leo Roi, Northport .....      |        | 12,761  |
| B. C. Copper, Greenwood ..... |        | 140,505 |
| Total .....                   | 26,226 | 696,578 |

The production of metals at the Consolidated Mining and Smelting Company's plant at Trail for April was \$507,068. Following are the figures in detail:—

Tons of ore received during the month of April ..... 35,590  
Tons of ore smelter during the month of April ..... 35,490  
from which were produced 410 tons of copper matte and 2,264 tons of lead bullion, containing:—

|              |           |
|--------------|-----------|
| Gold .....   | \$214,835 |
| Silver ..... | 101,891   |
| Copper ..... | 44,232    |
| Lead .....   | 146,110   |

Total gross production for April ..... \$507,068.

During April the refinery produced: Tons of pig lead, 2,012, valued at \$115,927; ounces fine gold, 2,663, valued at \$54,959; ounces fine silver, 148,128, valued at \$75,485. Total, \$246,371.

For the year beginning June 30th, and up to April 30th, the metals produced are valued at \$4,088,940, of which the refinery has produced \$2,096,461.

### TORONTO MARKETS.

**Metals**—June 8.—(Quotations from Canada Metal Co., Toronto):

Spelter, 5½ to 5¾ cents per lb.

Lead, 3½ cents per lb.

Antimony, 10 cents per lb.

Tin, 31 cents per lb.

**Copper**—

Casting, 14 cents per lb.

Electrolytic, 14½ cents per lb.

Lake, 14¾ cents per lb.

**Ingot brass**, 12 to 14 cents per lb.

**Coal**—

Anthracite, \$5.50 to \$6.75.

Bituminous, \$3.50 to \$4.50 for 1¼ inch lump.

**Pig Iron**—June 8.—(Quotations from Drummond, McCall & Co.)—

Summerlee No. 1, \$21.75 (f.o.b. Toronto).

Summerlee No. 2, \$21.25 (f.o.b. Toronto).

Midland No. 1, \$17.75 to \$18 (f.o.b. Midland).

An upward tendency is apparent in the iron market.

## Amatite ROOFING

SEND FOR A FREE SAMPLE

If you will write to-day for a free sample of Amate, the end of your roofing troubles is in sight. It is the one roofing that *needs no painting* after it is once laid on the roof.

If you would sit down and figure out exactly how much it cost to paint a smooth surfaced roofing during its life, you would find that the cost of this paint is *more than*

the roofing itself.

Amate, on the other hand, has a real mineral surface, and we sell the goods on the broad statement that it *needs no painting of any kind*.

The man who puts Amate on his buildings is insured against leaks and trouble for many years to come.

Send name and address for a sample and booklet, which will prove conclusively how much better Amate is than the old-fashioned "rubber roofings" which require constant painting and care to keep them tight.

PATERSON MANUFACTURING CO., Limited

Toronto, Montreal, Winnipeg,  
Vancouver, St. John, N.B.  
Halifax, N.S.

## On Your Crushers use Harris Heavy Pressure Bearing Metal

Will not Crack, Beat out or Break in your Bearings. Reduces Friction to a minimum. This Bearing Metal will give absolute satisfaction in your Crusher Bearings.

# NEW BOOKS on MINING, METALLURGY POWER GENERATION

## Principles of Mining

Valuation—Organization—Administration

Copper, Gold, Lead, Silver, Tin and Zinc

By Herbert C. Hoover, E. M.

200 pages, 6 x 9, illustrated, \$2.50 (10/6) net postpaid

Published April 1909

## A Manual of Underground Surveying

Loyal Wingate Trumbull, E. M.

Consulting Mining Engineer; formerly Professor of Mining, University of

Wyoming; formerly United States Deputy Mineral

Surveyor for Colorado

Over 250 pages, 6 x 9, fully illustrated, \$3.00 (12/6) net postpaid

## Mining Methods in Europe

By Lucius W. Mayer

Mining Engineer

170 pages, with many illustrations, \$2.50 (10/6) net, postpaid

This book places the latest information at the disposal of mining engineers and mining men. It is a most valuable piece of work and of the greatest importance to the mining man who seeks more economical and practical methods.

The illustrations from photographs taken in the mines by the author are a striking feature.

## The Study of Ore Deposits for the Practical Miner

With descriptions of Ore Minerals, Rock Minerals and Rocks.

A Guide to the Prospector.

By J. P. Wallace, M.D., E.M.

Member of the American Institute of Mining Engineers, and the

Colorado Scientific Society

Over 350 pages, 6 x 9, with over 100 illustrations, cloth \$3.00 (12-6) net

Leather edition, pocket size, thin paper, \$3.50 (15s) net

## McNeill's Code

(1908 Edition)

\$1.00 net postpaid

This new edition does not contain a single code word appearing in the former edition. It is brand new, with a great many additions and is the best general code offered.

It covers the mining field with the greatest thoroughness and meets all requirements of all business. It is three times as large as the old edition. The terminal index is embodied in this code.

## Notes on Metallurgical Mill Construction

Edited by Walter Renton Ingalls

256 pages, 6 x 9, cloth, \$2.00 (8/6) net postpaid

A New, One-Volume Edition of

## The Nature of Ore Deposits

By Dr. Richard Beek

Professor of Geology, Mining Academy, Freiberg

Translated and revised by Walter Harvey Weed

Formerly published in two volumes. Now issued in one volume.

\$6.00 (125s) net postpaid

## Millwrighting

By James F. Hobart, M. E.

400 pages, 6 x 9, fully illustrated, \$3.00 (12/6) net postpaid

(Published March 1909)

## Notes on Lead and Copper Smelting

Revised to November, 1908

By Hiram W. Hixon

163 pages, 6 x 9, \$3.00 postpaid

## Copper Mines of the World

By Walter Harvey Weed

Price \$4.00

## Principles of Copper Smelting

By Edward Dyer Peters

Price \$5.00

## The Metallurgy of Steel

By Bradley Stoughton

Price \$3.00

## The Manufacture and Properties of Iron and Steel

By Harry Huse Campbell

Price \$5.00

## A Manual of Fire Assaying

By Chas. H. Fulton

Price \$2.00

## Hydrometallurgy of Silver

By Ottokar Hoffman

Price \$4.00

## The Electric Furnace

By Alfred Stansfield

Price \$2.00

## Mining, Mineral and Geological Law

By Chas. H. Shamel

Price \$5.00

## Mine Timbering

By Sanders, Parlee, Macdonald and others

Price \$2.00

## Simple Mine Accounting

By David Wallace

Price \$1.00

## The Gas Engine

By Cecil P. Poole

Price \$1.00

## Gas Power

By F. E. Junge

Price \$5.00

## Producer Gas and Gas Producers

By S. S. Wyer

Price \$4.00

## Tulley's Handbook on Engineering

(Steam and Electrical)

By H. C. Tulley

Price \$3.50

## Motor Troubles

By E. B. Raymond

Price \$1.50

## Steam Turbines

By Lester G. French

Price \$3.00

## The Power Handbooks

Per volume \$1.00. Monographs on the following subjects:  
Shaft Governors Pumps Shafting, Pulleys and Belting  
Erecting Work Knocks and Kinks Engine-Room Chemistry  
Boilers Pipes and Piping Steam Turbines

## The Copper Handbook, Vol. VIII.

A Manual of the Copper Industry of the World

1,500 pages, 5¼ x 8½, price \$5.00

## Mineral Resources of Canada

140 pages, 7½ x 9½; 32 color engravings; mineral map of Canada

Price: paper \$1.00, cloth \$1.25

## The Dominion Coal Company

An Historical and Descriptive Brochure

By F. W. Gray

Price \$1.00

## IMPORTANT BOOKS IN PREPARATION

Volumes III and IV of

## Ore Dressing

By Robert H. Richards

Professor of Mining, Massachusetts Institute of Technology

2 Vols., 600 pages each, 6 x 9, fully illustrated, per Vol. \$5.00 (21/-)

net postpaid

(Scheduled for publication June 1909)

## Timbering and Mining

By W. H. Storms

6 x 9, fully illustrated, \$2.00 (8/6) net postpaid

(Price subject to change. Scheduled for publication June 1909)

## Electro-Magnetic Ore Separation

By C. Godfrey Gunther

6 x 9, fully illustrated, \$3.00 (12/6) net, postpaid

(Scheduled for publication May 1909)

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

# Geological Survey

## **PUBLICATIONS**

The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects

### **MARITIME PROVINCES**

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

### **QUEBEC**

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the province north of the St. Lawrence are also available.

### **ONTARIO**

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

### **THE PRAIRIE PROVINCES**

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

### **BRITISH COLUMBIA**

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

### **YUKON**

Many of the important areas in the Yukon have been reported upon and mapped.

### **THE NORTH-WEST TERRITORIES**

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

*Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.*

### **THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:**

#### **NOVA SCOTIA**

- 1019 City of Halifax Sheet.  
1025. Waverley Sheet.

The above two sheets belong to the regular series of Nova Scotia map sheets on a scale of one mile to one inch. The first includes Halifax City and Harbour, the second the Waverley Gold District.

#### **ONTARIO**

1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

#### **BRITISH COLUMBIA**

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shews the geology and location of veins.

1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch, by W. H. Boyd.

NOTE.—Maps recently published may be had on linen cloth for use in the field at the price of 10c. per copy.

### **REPORTS**

1072. Summary Report of the Operations of the Geological Survey for year 1908.

The Geological Survey, under certain limitations, will give information and advice upon subjects relating to general and economic geology. Mineral specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

*Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.*

# Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite ; copper in sulphide and native form ; gold, mostly in free milling quartz ; silver, native and in other forms ; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,  
**Toronto, Canada.**

# PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are : Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc ; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows :

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unsurveyed territory, is open to prospecting.

**Miners' Certificates** good for a calendar year may be obtained by sending \$10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minimum being 40 acres in unsurveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of \$10.00 plus a yearly rental of \$1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed

territory may be purchased as a mining concession at the price of \$20.00 per acre if within 20 miles of a railway in a straight line, or \$10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

**The Hon. Minister of Colonization, Mines and Fisheries**  
Quebec.

## Going Prospecting?

When you are miles away from the nearest assay office, you are sure to run across some ore that looks good, yet you have no means of accurately determining its value. Then you will realize what

## Way's Pocket Smelters

will do for you. With the use of one of our outfits, you can make a test in five minutes and know what your ore contains. This test will only cost five cent, and if your ore contains values, you make your location then and there. If not you waste no more money on it. Better than waiting two weeks for returns from an assay office, and twenty times cheaper.

Write to-day for Folder

**WAY'S POCKET SMELTER CO.**

P.O. Box 954

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Minerals or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579,03 the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 100,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

W. W. CORY, Deputy of the Minister of the Interior

### NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

### "WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. It does not freeze, or rather, explodes with perfect efficiency when frozen and needs no thawing.

### "AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

### PERMITTED EXPLOSIVES for Coal Mines

**Nobel Monobel, Saxonite and Carbonite.**

A letter or telegram addressed to the head office or any of the following agencies will receive prompt attention.

## SULLIVAN COAL PICK MACHINES

attain their superior cutting capacity and economy by means of a positive valve motion, operated from the piston. This device secures a hard blow with slow recovery, enabling each stroke to be placed at the proper spot. An air cushion prevents waste when running off the coal.

Runners prefer Sullivan Punchers because the positive valve aids them in handling the machine.

Send for a comparison of the cost of hand vs. machine mining, Catalog No. 657.

### What a User says of the Deister:

I have yours of the 7th inst and am pleased to advise you that the results obtained at our Calvario mill with the Deister No. 3 Concentrating tables under my personal observation in treating the ores from the Carboncillo mine were not only satisfactory but have made it possible for us to treat one of our low grade ores at a good profit which heretofore could not be treated except at a loss. Ours is a gold-silver ore which was given to your table through an 80-mesh screen at the rate of about 12 tons per 24 hours. The table requires but very little attention and from our experience I am convinced that there is no machine now in use which could give us the results obtained. Neg. Minera "El Carboncillo y Anexas, S. A.," Zacualpam, Mexico. Yours truly, (Signed) A. C. Chabaud, Mgr.

## THE ASBESTOS MERGER.

The article on Amalgamated Asbestos that appeared in our issue of June 15 has aroused much comment. The Montreal newspapers, in conformity to that cheerful habit of most newspapers, have published either disconnected excerpts from the article, or have opened their columns to anonymous critics who make no possible attempt to meet the facts as presented by Mr. Harpell.

Here it may be wise to degress for a moment. In our May 1st issue we published an article outlining the scope and plans of the Amalgamated Asbestos Corporation. The material for this article was supplied by Mr. Fritz Cirkel. We accepted it without misgiving.

It is patent that if the Canadian Mining Journal is to fulfill its mission in Canada, it must publish nothing that tends to mislead or misrepresent. Our aim is, has been, and will ever be, to give the facts as we find them. Shortly after our May 1 issue appeared we received information indicating that Mr. Cirkel's data were incorrect. Immediately we took steps to get at the truth. This was set forth in Mr. Harpell's article. And that this article is correct in its details and conclusions we have daily more reason to believe. The newspaper criticisms, inasmuch as they avoid carefully all essentials, merely strengthen this impression.

These considerations lead us to another that is most vitally important. To our knowledge the promoters of the merger have based their prospectus, not upon the report of a disinterested mining engineer, but upon the statements and opinion of a man, Mr. Fritz Cirkel, who is an owner of asbestos properties himself and is interested financially in the Merger. This is contrary to the rules of decent business. It is particularly out of place in a \$25,000,000 flotation.

We do not know the precise conditions under which Mr. Cirkel is employed by the Mines Branch of the Federal Department of Mines. We believe that his contract permits him to undertake private work in addition to his official duties. But, whatever the arrangement, the position in which he has placed himself and the Department is most regrettable. In the first place, Mr. Cirkel, acting as a Government official, enjoys privileges that would by no means be his as a private individual. Secondly, his position as a Government technologist has given him, through his departmental publications, a standing that cannot be gained otherwise. Thirdly, for both these reasons very serious responsibilities have devolved upon Mr. Cirkel. It is incumbent upon him that he should, so far as possible, distinguish between his work as an employee of the public and his efforts as a private mining engineer

This Mr. Cirkel has failed to do. Not only has he failed to recognize his responsibilities, but he has used, and has permitted others to use, his official status for precisely those purposes that are most opposed to the usefulness of the Department of Mines and to the welfare of the mining industry as a whole. In lending his name, officially, to Amalgamated Asbestos, Mr. Cirkel ceased at once to merit the confidence of the Department that employs him.

It is not our intention to animadvert upon the moral phases of this incident. It suffices to say that Mr. Cirkel has been lamentably indiscreet, officially and professionally. It remains for the Minister of the Department of Mines to clear up a situation that is false and unsavoury. We have every confidence that he will do this right speedily.

### THE FORMATION OF COAL.

Two remarkable papers appear in the May bulletin of the Canadian Mining Institute. Both were read at the last Annual Meeting in Montreal.

At that meeting there was practically no opportunity for giving these papers the discussion that they fully deserved. We hope that our readers will take advantage of our columns to effect a thorough exchange of views on the vital phases touched by these two contributions to modern scientific thought.

"Some Possible Chemical Changes in the Formation of Coal" is the title of Mr. D. B. Dowling's essay. The second paper, "Petroleum and Coals," which has already been reproduced in the Canadian Mining Journal, is from the pen of Mr. Eugene Coste. We shall glance at Mr. Dowling's paper first, and then allude to a few points that connect the two.

To the application of pressure and heat upon vegetable remains we owe the substances called coal. By a series of ingeniously plotted diagrams, Mr. Dowling illustrates the successive effects, first, of the charring of wood; second, of the gradual extraction of hydrocarbon compounds from peat; third, of the extraction of carbon dioxide; fourth, of the extraction of carbon dioxide and methane in equal parts and in various combinations with ammonium; and, lastly, of the extraction of water and carbon dioxide, and of water alone.

Of all the results arrived at, that due to the extracting from peat of seven to nine parts of water and one part of carbon dioxide, appears to duplicate most closely the natural process of coal-making. To quote Mr. Dowling: "That the greater amount of the change in formation of our coals is due to the slow process of water extraction, seems evident from the fact that the ash in the coals is not increased to a very much greater extent over that for vegetable matter than this theory would allow; and, secondly, that very few geologists will allow that the vegetable remains

associated with the coals have lost a great percentage of their carbon."

Mr. Dowling's deductions throw a clear side-light upon Mr. Coste's argument for the inorganic origin of petroleum. Mr. Coste contends that the geological history of coal is known sufficiently well to leave no room for belief in the organic origin of liquid hydrocarbons. The successive steps in the formation of coal from vegetable matter have been traced and recorded. The distillation of liquid hydrocarbons from these coals implies a large loss of carbon. All available evidence proves that this is not the case. Mr. Dowling demonstrates—for according to our present knowledge his paper amounts to a demonstration—that the loss of carbon in nature's laboratory is very slight.

This is one item on the credit side of Mr. Coste's ledger. It is a significant item, as it comes from a totally independent source.

### PROSPECTING AND HOLIDAYS.

No country in the wide world affords so many clean opportunities for out-of-door holidays as does Canada. It is to be regretted that as a nation we do not use these opportunities to better advantage.

In many respects our holiday making is not only unproductive of good, but is actually a source of harmful waste. Our fatuous popular resorts and the gladiatorial games that we have copied largely from the United States, do not make for wholesome recreation.

Nothing is more noticeable than the energy with which transportation systems encourage the holiday instinct. Throughout the summer every week end is marked by the migration of hundreds and thousands of people from the crowded centres of population to suburban places of amusement, more correctly described as places of excitement. In this manner a truly enormous expenditure of money and time is incurred, mostly unprofitable, directly and indirectly, so far as the people themselves are concerned.

Suppose now that a fraction of the attention that is centred upon highly artificial forms of entertainment were diverted to the object of introducing Canadians to their unique heritage—untouched expanses of forest and prairie, threaded everywhere by noble waterways and gemmed with innumerable lakes. In other words, suppose that there came a national awakening to the need of learning more about the meaning of our undeveloped resources.

Prospecting is popularly supposed to consist in the search for the ores of valuable metals. Prospecting should be more than this. It should be the vocation of thousands of Canadian youth. Mineral veins are by no means the only or necessarily the most remunerative discoveries that the prospector may hope for. Clay deposits, marl beds, timber, farm lands, these are but a few of the objects for which the prospector may

search. And searching of this kind is work that brings its own reward whatever the tangible results may be.

Let us imagine that our railway corporations, instead of catering to the frivolous impulses of the masses and classes, were to begin a sane campaign with the object of interesting Canadians in finding out for themselves the hidden wealth of our country.

The results of such a campaign may be left to the imagination. Cheap rates for prospectors we have advocated before. This would be but an item. Should the time arrive when Canadians are fitted mentally and physically to explore our boundless stretches of unknown lands, our nations will have nothing to fear from enemies without. The vast gain in physical and moral well-being would be accompanied by an immensely increased national freight traffic. Everywhere the effect of these conditions would be reflected. Let us, then, pray for the day when our national spirit shall wake to the meaning and possibilities of prospecting.

### SAMPLING OF COBALT ORES.

Our readers will notice elsewhere in this issue an article from Dr. A. R. Ledoux on sampling Cobalt ores. Dr. Ledoux is easily pre-eminent as an authority on subjects of this kind. At our request he has embodied in this article his experience and conclusions in regard to the peculiarly difficult silver ores of Cobalt. The elaborate precautions that must be taken to ensure a fair sample are set forth. This makes impressive reading.

"In the very beginning," writes Dr. Ledoux "we learned that this ore constituted a class by itself and could not be sampled accurately by ordinary methods, due very largely to the presence of nuggets and smaller particles of native silver, and to the fact that the silver is very unevenly distributed."

The fact that Dr. Ledoux does not employ mechanical samples is a point to which we would draw special notice. The limitations of mechanical samplers are not generally known. That Cobalt silver ores may not be amenable to fair mechanical sampling, is an inference from Dr. Ledoux's article.

We invite discussion of this and other points touched upon.

### PREVENTION OF GOLD STEALING.

Steps are being taken by the Victoria (Australia) Chamber of Mines to amend the Gold Buyers' Act (1907) at present in force in that State. Preventive legislation of this kind has especial interest for Canadian mine owners. For some years Nova Scotian operators have made vain attempts to promulgate laws that will make thorny the path of the gold-stealer. Similarly, the Cobalt mine managers have tried to

tackle the task of preventing the pilfering of silver. The Department of Justice, at Ottawa, has moved slowly in the matter. But hopes are entertained that effective measures will soon be adopted.

A few notes concerning the condition of affairs in Victoria will throw useful light upon the subject. On March 2, a conference was held at Bendigo for the purpose of discussing the prevention of gold stealing. Representatives of the Mine Owners' and Mine Managers' Associations were present. So also were representatives of the labor union—the Amalgamated Miners' Association. It appears that investigation had revealed the fact that about 30,000 ounces of gold had been stolen and disposed of to buyers not identified with the regular banks. This was announced from the pulpit by a Rev. Mr. Worrall. Immediately a storm of angry protest arose. The conference was called to look further into the matter.

It was expected that the members of the Association would do all in their power to remove the cloud thus cast upon them. Strange to say they would consent to nothing except conditional co-operation. Although they recognized full well the very serious position in which their whole Association was placed by these revelations of wholesale peculation, they proffered the following bargain:

"The Miners' Association is willing to co-operate (in the prevention of gold-stealing), in the expectation that the mine owners will give preference to unionists and abolish the black list."

In other words the miners were content to permit dishonesty to flourish in their own ranks unless they could impose their own conditions on the operators.

This short-sighted policy, this willingness to sacrifice principle, is too often the sign-manual of labor organizations. Particularly is it characteristic of one body, the United Mine Workers, a United States organization that is now making desperate attempts to gain control of Canadian miners. We believe that morally and socially our Canadian labor organizations are healthier than those across the border. For this and other reasons we shall continue to oppose the encroachment of the U. M. W. upon Canadian territory.

### ONE PROSPECTUS.

The prospectus of the Northern Star Mining and Development Co., Limited, 197 Sparks Street, Ottawa, has been submitted to us. It is a thing of beauty.

The prospectus attributes to the vice-president, Mr. C. W. Willimott, experience and attainment that he does not possess. Mr. Willimott was attached to the staff of the Geological Survey for some years. The following statement is made on page 10 of the prospectus: "During the latter part of his service with the Canadian Government, all minerals brought to that office were referred to him for identification. His 38

years of experience as mineralogist on the Geological Survey has furnished him with knowledge that will be worth untold wealth to the Company."

Far be it from us to appraise Mr. Willimott's value. It is for us to contradict flatly the assertions quoted. The statement that all minerals brought to the survey were submitted to Mr. Willimott, is false. Further,

Mr. Willimott did not have 38 years' experience on the survey. He never was mineralogist, nor was he at any time a technical officer.

As Mr. Willimott's signature is attached to this document we wish to inform him that he has ample grounds for proceeding against whomsoever is responsible for subscribing his name to patent lies.

## SAMPLING OF COBALT ORES.

By Albert R. Ledoux, Ph.D.

[Editor's Note.—This article was written at the special request of the Canadian Mining Journal.]

The first carload of Cobalt ore was received at Ledoux & Company's sampling works, at the port of New York, in February, 1905, although specimens and samples had been submitted to us in January of that year. In the very beginning we learned that this ore constituted a class by itself and could not be sampled accurately by ordinary methods, due very largely to the presence of nuggets and smaller particles of native silver, and to the fact that the silver is very unevenly distributed.

In Volume X. of the Journal of the Canadian Mining Institute, appears a statement prepared by me, showing that up to that time, February, 1907, about 18 per cent. of Cobalt ores received at our sampling works had run between 1,000 and 2,000 ounces of silver per ton; 10 per cent. contained from 2,000 to 3,000 ounces; 4 per cent. from 3,000 to 4,000 ounces; 3 per cent. from 4,000 to 5,000 ounces; 17 per cent. from 100 to 200 ounces, and 11 per cent. below 100 ounces. The highest carload handled by us up to that time ran 7,402 ounces of silver per ton, and the next in grade were from 6,000 to about 7,000 ounces.

When one considers that this silver occurs largely in native form, and is an alloy with arsenic, nickel and cobalt, the difficulty of obtaining an accurate sample is manifest. We long ago discovered that to secure an accurate sample, the coarser part of the metallics had to be removed and treated separately. The method devised by us, and followed until recently, has been quite accurately described in the paper of Mr. F. F. Colcord, published in the Engineering and Mining Journal for December 22, 1906, but it may be briefly repeated as follows:

All the ore is passed through crushers and rolls in order to reduce the material as nearly as possible to one quarter inch size. Nuggets passing through the rolls, being malleable, tend to separate them, allowing some proportion of ore larger than quarter mesh to pass through. In practice, it was not found necessary to return these larger particles to the rolls, but we leave about ten per cent. of the material larger than quarter inch. The ideal preliminary crushing would be to have the whole material pass a quarter inch screen before proceeding further.

The ore passing the crusher and rolls, is piled in two parallel ridges, which we may designate as No. 1 and No. 2 by alternate shovelling to left and right. Large silver nuggets, and coarser pieces also containing silver, are picked out by hand for separate treatment. The two ridges contain substantially half a carload

each, and are shovelled together alternately into one long ridge for the purpose of mixing (ridge No. 3). This ridge is again "half shovelled" as in the beginning, to make ridges No. 4 and No. 5. No. 5 is then half-shovelled to make ridge No. 6, the alternate or rejected shovelfuls going back to ridge No. 4. Ridge No. 6, which now contains one quarter of the original carload, is half shovelled, making a pile or cone containing one-eighth of the original carload, the rejected half going back likewise to ridge No. 4. The resulting sample is coned up into what might be called pile No. 7 and quartered down to make pile No. 8, the rejected portion returning to No. 4.

Coning and quartering is then proceeded with until pile No. 9 is reached, which will weigh perhaps a thousand pounds, all the rejects having been returned in each case to ridge No. 4.

This thousand pounds, more or less is passed through a mill, including all the metallics which have remained with it. This mill grinds the material to about one-eighth mesh, including the metallics. The material, after passing an eight-mesh screen, is turned over with shovels three times and passed through a Jones sampler, reducing it to about 40 pounds, the rejects again returning to ridge No. 4.

This 40 pounds, which now constitutes the twelfth stage of sampling, is ground through a mill until it will pass a 20-mesh screen, thoroughly mixed and again divided into two parts, one of which is temporarily held at the works, in case of need, and the other sent to the laboratory.

In the laboratory, the sample is reground and sub-divided to a sample of about five pounds weight. After weighing this, it is ground in a pebble mill until it will pass a 100-mesh screen. The metallics which cannot be finely ground, are left on this screen, then weighed and suitably sub-divided to make final samples. The fines passing the 100-mesh screen are mixed and also sub-divided into several parcels, corresponding with the metallics. The final samples each consist of two parcels, one contains the metallics, the other the fines. The weights of fines and the weights of metallics from the five pound sample, are recorded on each package, so that the final assays may be calculated.

The rejects, forming ridge No. 4, represent every portion of the original carload except the negligible 40 pounds taken for a sample. The second sampling proceeds as before and finally a third sampling, and a fourth, so that four samples are taken from each carload, differing in no respect from one another, excepting that each one is taken from a bulk of a few pounds less in weight than the preceding samples.

That the average assay of the four samples accurately represents the lot, has been proved again and again by the reasonable concurrence of the assay result, as for example, in three lots:

|                      |         |         |         |
|----------------------|---------|---------|---------|
| First sampling.....  | 3840.00 | 3765.80 | 5090.10 |
| Second sampling..... | 3822.80 | 3696.60 | 5119.60 |
| Third sampling.....  | 3829.60 | 3703.80 | 5121.60 |
| Fourth sampling..... | 3644.10 | 3729.90 | 5130.40 |

The metallies, which have been obtained by hand-picking the larger pieces of silver from the original lot before sampling, are weighed and handled separately as bullion. They do not constitute part of the sample taken from the crushed ore, but are melted and treated separately.

The sampling at our works is usually performed in the presence of representatives of buyers and sellers, and the former, especially, are men of long experience in the handling of ores, both at western sampling works and smelters in the east.

Suggestions have been made to us from time to time as to what might improve the process in the direction of accuracy, and in some cases, the not unnatural question has been asked why we do not employ mechanical sampling from beginning to end, if for no other reason than that it is cheaper than hand labor. Such mechanical sampling has been installed at Copper Cliff, as is well known, and the methods and results are well described in the Journal of the Canadian Mining Institute for 1908, in a paper prepared by Mr. Arthur A. Cole, of Cobalt. Mechanical sampling is likewise employed on Cobalt ores at Deloro and at Denver. In the sampling of ordinary ores, mechanical sampling long ago superseded hand sampling in all progressive works, both east and west, but there seems to be some question in the minds of assayers and others interested, as to whether the mechanical sampling produces as uniform results in Cobalt ores as does the method of shovelling into ridges and cones, as outlined above. If there be anything in the belief that mechanical sampling is not quite the equal of hand sampling on this ore, it rises from two causes:

One, the possibility that in grinding in a Ball mill or other similar device, there may be a mechanical concentration in the mill, rendering it difficult to get samples which do not show too high or too low a proportion of silver; and to another cause: that automatic sampling devices, cutting out a fraction of the lot, which is subsequently sampled down by any method, do not admit of taking more than one sample of the "whole" lot, starting practically from the beginning each time. The assumption is that the fraction taken mechanically must accurately represent the whole. In many works, mechanical samplers are set to take out one-tenth, and from two to four samples of this tenth are subsequently cut out for duplicate or quadruplicate assays, but by the slower and more tedious hand sampling, four "original" samples may be taken, starting in each case from the beginning.

Without going into all the reasons for such changes as from time to time have been introduced by Ledoux & Co., I would say that our present practice is substantially as follows, and details omitted being evident from what has preceded:

The material after being unloaded, is put through a Blake crusher, crushing the ore to about one and one-fourth inches in size. From there it runs down a chute into an elevator boot, the buckets raising and

throwing the ore into a one-inch revolving screen and passing through this into an outer screen of one-half inch holes. All that passes through this screen drops into a chute and is ready for the floor. The material not passing through this half-inch screen, together with all which has passed through the one-inch, slides through a chute into the rolls, which are set to one-fourth inch; all material not passing through the one-inch screen passes down a chute to a crusher, thence back to the elevator and so on, until all the material has been crushed and passed through the rolls. The ore after leaving the rolls, is wheeled with barrows onto the sampling floor, and put into two ridges, alternating each barrow, one to the right and the other to the left, then screened through a half-inch mesh, and all the metallies which do not pass the half-inch screen, are picked out and treated separately. Men are then placed at each ridge opposite each other, shovelling the material into one ridge.

The ore is then half-shovelled by throwing one shovelful to the right for one ridge and the other to the left for the other ridge. After dividing into two ridges, each ridge is again divided by half-shovelling to about two tons, which is coned and quartered down to about one thousand pounds remaining, and put through the rolls and mills until all the material, including the metallies, will pass through an eight-mesh screen. This is then mixed by shovelling over three different times, then put through a Jones sampler and worked down to about 35 or 40 pounds, which is put through a Hance Brothers & White drug mill and ground to pass through a 20-mesh sieve. This is sent to the laboratory and treated as described above.

It will be seen that in the second method of sampling the ore after crushing is thoroughly mixed and then divided into four lots or parcels, each of which should be exactly like the others. Each of these four lots or samples is then worked down separately, and the average of the assays of the four lots is taken as representing the carload. The reasonable concordance of the four samples is shown by the following examples, on two lots:

#### Ounces of Silver per Ton.

|                      |         |         |
|----------------------|---------|---------|
| First sampling.....  | 3956.80 | 3001.10 |

### NEW ZEALAND GEOLOGY.

Under the energetic management of Dr. J. M. Bell, director of the New Zealand Geological Survey, the geology of that country is receiving much more systematic attention than ever before. A new series of elaborate bulletins is being brought out, covering gradually the whole dominion. Bulletin No. 7, "The Geology of the Queenstown Subdivision, Western Otago," has just been received. In this, Mr. James Park, Professor of Applied Geology at the University of Otago, outlines the geology of the Queenstown subdivision. The report contains 112 pages of letterpress, 38 plates, 33 illustrations, and 13 maps.

In glancing over Mr. Park's notes on the economical geology of the Queenstown region, several interesting features are noticed.

The most productive gold-bearing lodes of the Mace-town district are enclosed in a comparatively soft, grey,

silky mica-schist. The gold occurs in shoots of quartz, the remainder of the lode being filled with crushed country rock. The veins are fissures with well-defined walls, the hanging wall being the more regular. The ore is free-milling, carrying varying amounts of pyrite and mispickel. The pyrite may be either barren or gold-bearing. The tendency of the lodes is to come together at depth. Where horses of country rock (locally

called "mullock") are encountered in a lode, they occasionally show small veins or stringers of quartz of considerable richness. Occasionally, also, there are small veins of quartz running into the country rock.

In some places the stopes require very careful timbering; in others a very slight amount is sufficient. The stopes are generally taken out in 7-foot bunches and filled in again with waste to prevent subsidence.

## COAL MINING IN SOUTH-WESTERN VIRGINIA.

By D. A. Patterson.

[Editor's Note.—This article will be read with interest by Eastern Canadian coal producers, since it has a direct bearing upon certain questions of the day.]

Among the mountains in the western part of Virginia lies a district known as the Big Stone Gap Coal Field, which is from year to year making greater impress on the minds of those interested in the future development of the coal industry. Here, in the counties of Lee and Wise are operations building up which make abundant promise of forming a coal mining and coking centre which will equal that of the Connellsville district in Pennsylvania. It is the intention of the writer to give, at the present time, a description of one of the above-mentioned concerns, which has been constructed during the past two years, and which is equipped with all modern devices for the economic production of coal and coke.

The Keokee Coal & Coke Company, of Keokee, Virginia, is fortunate in possessing a property of 8,000 acres with seven workable seams, containing approximately 300 million tons of coal varying in thickness from 48 to 96 inches. All coal on this property dips uniformly to the northwest on a grade averaging 2 1-2 per cent., nothing greater than 3 per cent. having been encountered up to the present. On account of the high altitude (2,500 feet) and nearness to the top of the mountain range, all mines are free from excess water; one triplex electric pump discharging all water through a two-inch line. The top, for the most part hard slate, although grey sandstone has been encountered on occasions, is of such superiority that props are used only in rooms which are driven 20 feet wide. No timbering in the main headings has been necessary. Two seams are at present being mined; one known as the McConnell, and one as the Wilson seam; the first mentioned seam being a superior coal showing an analysis of—

|                    | Coal. | Coke. |
|--------------------|-------|-------|
| Moisture .....     | 3.86  | 0.69  |
| Vol. matter .....  | 34.13 | 0.93  |
| Fixed carbon ..... | 56.39 | 90.33 |
| Ash .....          | 5.62  | 8.05  |
| Sulphur .....      | .79   | .65   |

Both these seams outcrop on the sides of the mountain and consequently give opportunity for rapid development and minimum cost in operation. Mining is done on the four entry system, the two sides of the mine being kept entirely separate; and butt entries are driven right and left on 350 feet centres.

From the mines the coal is hauled by 12-ton Goodman electric locomotives over a tramroad 3,500 feet to the tippel which was designed and built by Heyl

& Patterson, of Pittsburg, Pa. The plant is electrically equipped throughout; 3 1-2 ton gathering locomotives are used for inside haulage; Goodman chain breast machines 44 inches wide and having an undercut of six feet, are used for undermining the coal, and electrically driven fans of 100,000 and 150,000 cubic feet capacity, built by Ira E. Stevens of Chicago, are used for ventilation.

The tippel contains several innovations which are of interest in that they have proved feasible. As the loaded cars from the two mines pass through the tippel at different elevations, they are dumped, two at a time without uncoupling, by rotary dumps. These dumps are a special design of the builders and are a departure in the handling of coal. Each dump consists of three cast steel rings connected by angle tie-bars. These revolve on six 16-inch cast steel wheels and are driven by a 10 h.p. motor through three spur gear reductions;

Club House and Physician's Cottage.

the master gear of the third reduction being a segmental gear attached to the central ring. The dump is started by the attendant throwing in a friction clutch and is automatically stopped at the end of each revolution. Much time is saved by this device, as coal can be loaded onto conveyors at the rate of 500 tons per hour; and the uncoupling of cars is eliminated by the use of swivel hitchings. Empty cars from the McConnell dump continue on round a spur of the mountain and return to the main line between the tippel and the mine. Return trips for the Wilson mine are switched back through the tippel behind the dump.

From the dumps the coal is deposited on pan-conveyors by means of reciprocating feeders. Coal from the McConnell Mine at higher elevation being conveyed under the Wilson dump, is kept separate from the Wilson coal which is carried on a parallel conveyor. Both

coals proceed to the crushing and screening house, at which point they are screened either separately or together; or pass on over veil plates and another set of conveyors to be loaded as "run of mine" or screened again at the railroad tracks. The screenings are deposited in a hopper which feeds two No. 4 Williams pulverizers where the coal is crushed for coking purposes.

Coke Drawing Machine.

poses and carried by belt conveyors to a bin having a capacity of 1,400 tons. The disintegrated coal is evenly distributed throughout the bin by a continuous running, automatic reversing, tripper, when desired run-of-mine coal may be unloaded from the first conveyors into a Heyl & Patterson breaker which passes the broken coal to the pulverizers for further disintegration. The tippie is designed to handle 5,000 tons of coal per day; the present output being 1,400 tons per day of ten hours.

Coal Tippie, showing elevation at which coal is dumped.

The Keokee Company has built 400 coke ovens of the "bee-hive" type. These are built in two parallel batteries of 158 ovens each, and one row of 84 bank ovens. Forty-six inch doors have been constructed to facilitate the operation of Covington coke-drawing machines. These machines do away with the laborious task of hand-drawing and, although inclined to break

the coke considerably, have advantages which more than offset the losses involved. At Keokee 40 ovens or 160 tons are drawn and loaded by each machine daily. All yard trackers are laid with No. 75 steel and built on a 1.25 per cent. grade, making it possible to place empty cars under the conveyors of the coke machines without the aid of a locomotive. For haulage the company have one 60-ton Baldwin locomotive.

Behind, and adjacent to, the bank ovens a large gas flue has been built. This collects all waste gases from these ovens and is constructed of three layers of brick, one silica, one fire, and one red. The gas, coming through connecting flues from the ovens, is utilized for steam purposes and after passing through the main flue goes under the fire boxes of the boilers and up behind the bridge walls; thus preventing any injurious effect of the gases on the grate bars. The boilers, of which there are four Wickes vertical, developing 300 h.p. each have the usual fire boxes so that they can be fired by coal, if necessary; but with the collected gases from 39 ovens, burning 48 hour coke, this has been found unnecessary. The supply of heat is regulated by water-cooled dampers placed in front of the fire doors. These

Rotary Dump, showing cars in position for dumping.

are operated by hydraulic pressure obtained from the feed pumps. Further information relative to the effectiveness of the above utilization of waste gases can be obtained later, as extensive tests are being made at Keokee by the Wickes Bros. Boiler Company. It is sufficient to say that there is a saving of from 25 to 30 tons of coal per day of 24 hours.

The power house, built of grey sandstone, with composition roof, is equipped with two 300 k.w. 250-volt Goodman generators driven directly by McEwen tandem compound engines which have given admirable service during the past year. An Ingersoll-Rand air compressor has also been installed to furnish power for air-lift wells, and one Latta-Martin displacement pump. All waste oil from the engines is piped to a filter below the floor. A concrete tank having a capacity of 100,000 gallons has been built in the vicinity of the boilers so that a supply of water for boiler feed can always be kept on hand.

Up to the present time 190 houses have been built for the use of miners. These are of a superior type with from three to seven rooms. The valley widens at this point, giving opportunity for the construction of buildings without the usual congestion found in

mining towns. All houses have lots measuring 75 by 150 feet.

Owing to the excellent quality of the coal in the Big Stone Gap region and its adaptability to coking, the field as a whole is essentially a coke producer. The character of the coal at Keokee makes it compare favorably with the famous gas and steam coals of the Pittsburg field which have earned very high reputations in the principal markets. There is a large coal

trade in the Carolinas and Georgia, and the manufacturing industries in these states are growing rapidly. Although the market for this coal is perhaps more limited than that for coke, its excellent quality together with favorable freight rates makes it an active competitor over an area of considerable extent.

The Keokee plant has been designed and constructed under the supervision of Mr. C. P. Perin, of New York, who is president of the company.

## GOWGANDA MINING DIVISION, DISTRICT OF NIPISSING, ONTARIO.

Notes from Preliminary Report by W. H. Collins, Geological Survey of Canada.

(Continued from last issue.)

### Local Distribution.

Valuable argentiferous veins were known in 1908 only in the Gowganda district, and, so far as yet known, discoveries have been confined to the diabase west of that lake. Most of them occur in the southern portion of the central diabase strip which lies a short distance from the shore and extends northward for about seven miles from Elkhorn Lake. On one of the Mann claims (T. R. 1966), now owned by Messrs. Foster, an east and west vein averaging 4 or 5 inches in width had been traced for 300 feet, the original discovery being made in the exposed face of a low diabase wall. At its surface the vein material had been weathered out for a depth of about 15 inches, and the cavity filled by a brownish mass of the decomposed matter mixed with vegetable mould and sand. Nuggets of mossy or arborescent silver were scattered richly through this dirt, and a fairly continuous spine of the same metal, sometimes an inch thick, extended along the middle of the crevice. On the adjoining claim (T. R. 1982), a vein of massive smaltite about 1 inch wide was seen; a little silver had been found at its surface, and streaks of argentite and disseminated grains of smaltite were seen in the wall rock. Aplite dikes on another claim were found to be stained by cobalt bloom, and full of disseminated chalcopyrite.

The properties owned by Messrs. Crawford and Dobie about half a mile farther south were not visited, but were generally reported to be of about the same richness as that in T. R. 1966. Immediately north of Hangingstone Lake, Mr. F. A. McIntosh was conducting active prospecting in a coarse gabbroid, locally syenitic, form of diabase, intersected by aplite dikes. A discovery of native silver has been made since then and the property sold to Messrs. F. R. Bartlett & Co., of Toronto, together with other claims located between the northeast and northwest arms.

No silver had been obtained in the eastern diabase strip, although the geological conditions appear identical and calcite veins are abundant. An exceptionally large vein, about 18 inches wide, and traceable across two adjoining claims was seen on the property of Messrs. McLaughlin and McIntosh, about half a mile northeast of the northwest arm. Mineralization in it near the surface was very slight.

In the western strip less exploration had been performed, and little could be learned about the ore deposits. Loose pieces of native silver had been found by

W. H. Margueratt in narrow fissures on Mr. R. 1798, but the vein material was not exposed.

Out side the Gowganda area systematic prospecting was in progress at only one point—Wapus Creek. Under the management of Mr. Robert Lett a group of nine claims was being stripped and trenched, with the result that numerous calcite veins had been traced through a diabase showing the same complex intermingling of basic and acid phases and aplite dikes as at Gowganda. Chalcopyrite and cobalt bloom were abundant, and smaltite had been found as disseminations in the wall rock. Lumps of native bismuth weighing several ounces had been taken from a fissure in an aplite dike, analyses of which showed it to contain silver.

Tentative exploration was being conducted along Duncan Lake and east of Firth Lake, but not with the closeness and persistence that the topography of these veins require. In general the veins seen on Duncan Lake are exceptionally rich in quartz, and gash veins are common. Chalcopyrite, pyrite, and galena are the most noticeable metalliferous minerals, but cobalt bloom stains are frequently observable.

### Future Possibilities.

The present knowledge of the Gowganda area indicates it to be highly mineralized, at least in so far as number of veins and surface showings are concerned. The number of discoveries within its area of ten square miles is steadily increasing. The area, character of the mineral association and the richness of the surface showings are comparable with those of Cobalt. There is a general similarity in the geological conditions. The mineralized veins in Gowganda occur in the diabase, as do some of the good Cobalt veins. There are, it is true, local differences, but the resemblances are more pronounced than the differences, and lead to the hope that exploitation will reveal similar underground conditions. The well mineralized veins are sufficiently long and uniform on the surface to suggest similarly persistent vertical dimensions. Further geological work may reveal something definite concerning the character and size of the diabase bodies which form the country rock, and thus afford a basis for predicting their subterranean distribution. While there are grounds for hoping that the veins will persist in depth, this has not yet been proved, nor, if this is the case, that the mineralization and values are also persistent.

The relative importance of Gowganda is therefore a matter of uncertainty as yet, but it may be confidently

firmly that for its state of development the outlook is very favourable, and the number of veins, area of mineralization and rich surface showings afford good grounds for hoping that some at least of the veins will be found to be commercially important.

The details of igneous intrusion, differentiation and mineralization may never be sufficiently understood to allow of accurate prediction regarding the location of silver deposits, but a general conception of the sequence of events culminating in their formation does permit of the formulation of certain criteria useful in the search for ores. Evidence is accumulating to show that the silver-cobalt mineralizations in the Temiskaming region are connected with a late stage of differentiation in the magma which supplied the quartz diabase and granite. It seems reasonable, therefore, to expect ore deposits in or near such bodies, especially if they are of large size and have undergone important chemical differentiation, that is, if they contain a varied and extensive association of basic and acid phases of the diabase. Pre-existing channels to receive the mineralizers are also necessary and their distribution a matter of vital importance, but in this region they appear to have been everywhere abundant.

These conditions appear to exist quite as fully at

other foreign matter. The ore body is thought to be of vertical tabular form, occupying a fissure-like space. Its limits are not known, consequently nothing can be yet stated regarding the commercial possibility of the deposit.

Specular ore also occurs in the basal conglomerate of the Huronian series, filling the interstices between the pebbles where an original cement was deficient. At the south end of Kenisheong Lake the conglomerate appears at the water's edge, and the hematite may be observed while paddling near shore. The same thing occurs at the narrows on Duncan Lake, just south of the central expansion. In neither case is the ore in commercially valuable quantity.

**Magnetite.**—Keewatin iron formation exists about one-half mile to the northeast of Gowganda Lake. A brief visit was paid to some claims belonging to Mr. Cryderman where the formation is well exposed. The Keewatin, which is partially overlain by Huronian and traversed by diabase, consists of dark grey or black, banded chert or quartzite associated with chlorite schist. The dark bands, usually only a few inches in width, are full of disseminated magnetite grains. No concentrations were noticed, and the richest bands would probably yield less than 30 per cent. metallic iron, con-

Diagram Illustrating Geological Relationships of Montreal River District.

several other localities besides Gowganda. At Wapusk Creek they seem identical and, indeed, results obtained thus far indicate that some mineralization of the silver-cobalt type exists. Between Duncan Lake and the West branch the conditions require further study, but, as now known, are not discouraging.

#### Copper.

The chalcopyrite is sometimes aggregated into bunches which yield ore specimens of such excellent appearance as to arouse interest. The ore is, however, confined to veins a few inches in width and so scattered as to render them valueless. Occurrences of this kind characterize most of the great diabase bodies, examples of which occur on Mosher Lake, between the northeast and northwest arms of Gowganda Lake and elsewhere. The chalcopyrite is sometimes superficially altered to malachite and azurite.

#### Iron Ore.

**Hematite.**—Excellent specular and kidney ore is known to exist a short distance east of Nest Lake, but the locality was not visited owing to the more urgent requirements of other portions of the district. Specimens of the ore obtained, however, proved to be of excellent character, with little admixture of silica or

sequently the present showings cannot be considered valuable.

#### Asbestos—Distribution.

In the Keewatin area between Firth and Obushkong Lakes there occur masses of a basic igneous rock through whose decomposition serpentine and asbestos have been developed. The localities given in connection with the description of the Keewatin may be briefly restated. Two bodies were found. One of these was traced for a width of four claims, but nothing learned of its north and south extent. It consists very largely of green serpentine traversed by a network of fine, white weathering veins of asbestos. More extensive outcrops exist along the east shore of Firth Lake. At somewhat more than a mile from the foot of the lake a considerable mass of partly decomposed wehrlite, serpentine, and asbestos is visible. The main mass is of dark green colour, the asbestos traversing it abundantly as a series of glistening bright green threads. The seams are small, none being found more than  $\frac{1}{4}$  inch in width, but the asbestos fibres are fine and elastic. The serpentine is often coarsely fibrous, but brittle.

#### Origin.

Microscopic examination shows the serpentine and asbestos to be the product of decomposition of the

wehrlite, a nearly black medium grained igneous type. Alteration has obscured its original character, but sufficient of the primary constituents remain to admit of its determination. It consisted of olivine, diallage, and common hornblende, with considerable ilmenite and apatite, but plagioclase is apparently absent. Hornblende and diallage form the basis of the section in which lie abundant rounded or idiomorphic grains of olivine. The latter is completely altered to a matted intergrowth of fibrous serpentine containing scattered grains of black iron ore. Diallage persists as colourless bi-refringent remnants enclosed by a felted mass of decomposition products, chiefly long scales of talc. The hornblende is fresher and strongly pleochroic, the tints being green; its alteration begins by bleaching, followed by development of colourless fibres of low bi-

refringence, possibly serpentine. Primary ilmenite is replaced by irregular patches of leucoxene, showing gridiron structure. The final product of alteration is a soft green serpentine rock composed almost wholly of that mineral.

The limits of these masses are exceedingly difficult to define, owing to the fact that they are associated with other Keewatin rock and basic forms of the post-Huronian diabase, to which it presents considerable resemblance. The asbestos actually seen is probably too short and small in amount to be valuable, but the high commercial value of this material renders delimitation of the wehrlite masses advisable. Asbestos of very good quality has been found by Mr. George Rahn in the vicinity of Sinclair Mountain, so that this mineral may be one of the district's latent resources.

## A REMARKABLE GERMAN ELECTRIC MINE HOIST.

By Frank C. Perkins.

Electric hoists of enormous power are now utilized to great advantage in German mines, the accompanying illustration showing the electric winding equipment of the Mauveschacht at the Heinitz pits, near Beuthen, in Upper Silesia.

This hoisting equipment includes an electric motor of the direct current type of Brown-Boveri construc-

The Mauveschacht mine hoist was designed to raise  $7\frac{1}{4}$  tons of coal from a depth of 2,530 feet at the above enormous rope velocity of about 2,000 feet per minute.

It may be stated that the drum shaft is provided with two heavy bearings, fitted with ring lubrication, these bearings being mounted upon a built-up wrought iron bed plate, together with the bearings of the motor.

tion, having a maximum capacity for an overload of 1,400 horsepower, the normal output being 565 horsepower. It operates on a circuit of 480 volts, with a speed of 24 revolutions per minute, and is directly coupled to the Keepe drum, which is  $26\frac{1}{4}$  feet in diameter, provided with a balance rope having a velocity of 1,980 feet per minute.

The hoist is situated at a distance from the power station, which also supplies electric current for pumping electric ventilation, and for operating other motors about the colliery. This electric mine hoisting system was specially designed to take advantage of the good governing properties of the turbine generating plant, whereby the fluctuation in the input of the hoisting

motor supplied by it are transferred directly to the boiler plant, without causing under variations in the speed of the turbines, and at the same time with the auxiliary equipment ensuring good economy from the steam turbine.

This electric hoist is supplied by its own generator, which is driven by a steam turbine of the Brown-Boveri type, with a separate exciter, which also excites the field of the hoisting motor, as well as the field of an alternator directly connected to the same steam turbine.

The turbine operates under a steam pressure of 135 pounds per square inch and 275 degrees C., the exhaust being connected with a vacuum of 90 per cent. at the turbine to the central condensing plant.

An interesting point in connection with this steam turbine is that it admits steam at boiler pressure into the secondary expansion of the turbine, in accordance with the requirements of the hoisting motor automatically, it being provided with a by-pass, which is self-acting.

It will thus be seen that the load variation due to the hoist comes directly upon the boiler without any intermediate machinery between the mine hoisting motor and the turbine-driven generator. It will be noted that this arrangement acts as a natural accumulator or storage, the peak loads being taken care of by the boilers, which are provided with stored steam. There are a great many advantages in this method of working electric mine hoists, as it is simple, safe, and reliable, avoiding rotating flywheel masses and the intermediate machinery, and is at the same time low in cost for installation. The conversion and storage losses of the other electric mine hoisting system are avoided, and there is good economy in the steam turbine set during the intervals when electric energy is not utilized for electric hoisting by the connection of the steam turbine to the second electrical generator.

It is stated that the Mauveschacht electric hoist can be doubled as to capacity by directly connecting to the hoisting drum a second electric motor on the other side, if desired.

At the present time the electric hoist is only required to raise about one-half the above-mentioned load of coal at the high rope velocity previously stated from a depth of 1,770 feet. When the electric hoist was installed it was decided to provide for two installations, the second being added when the pit is fully developed at a later period, the shaft of the winding drum being provided with a coupling at each end.

At the present time only one end is equipped with a motor, which is capable of developing, as above mentioned, an overload of 1,400 horsepower without injury for short intervals.

This high-power electric motor is of the direct current, separately-excited type, and is mainly controlled by regulation of the generator voltage. The pressure at the motor terminals is varied from zero to 480 volts by means of a regulator in the field circuit of the generator, this arrangement reducing to a minimum the rheostatic losses. It may be stated that the main terminals of the motor are directly connected to the steam-turbine-driven, direct-current generator, and there is thus avoided all losses and annoyance of switching in main circuit regulation.

The steam turbine, as above mentioned, also drives a second generator, which is an alternator, supplying current for other motors at the mine, this second dynamo being driven in tandem with the generator which supplies the hoisting motor, and is a most essential part of this system of electric mine haulage, which allows the steam turbine to always be operated with high economy on account of the constant load it provides.

## THE DETERMINATION OF TUNGSTIC ACIDS IN LOW-GRADE WOLFRAM ORES.\*

By H. W. Hutchin, Associate, and F. J. Tonks, Student.

The determination of small quantities of tungstic acid by known methods is difficult, besides involving considerable time and labour. The new method described herein combines the accuracy of the mercurous nitrate method with an improvement in the attack of the mineral; viz., fusion with alkalis is replaced by digestion with caustic soda solution. The advantages gained are in time, accuracy and general utility. A single assay of a sample of ore may be completed in 2½ hours; six or more assays may be worked in a batch as easily as one. The preliminary treatment with hydrofluoric acid becomes unnecessary. The charge of ore is not limited to 1 or 2 gm., but as much as 20 gm. may be used if necessary. The use of a large charge secures greater accuracy in the determination of tailings values, exactly where accuracy is most needed.

The paper is divided into two sections. Section I. deals with the working details of the assays employed

and the tabulation of results for comparison. Section II. is supplementary and mainly an investigation of conditions affecting the two principal assays, viz., the aqua regia method and the new method.

### Section I.

The methods of analysis in common use are:—

1. The aqua regia method.
2. Aqua regia method with previous treatment with hydrofluoric acid.
3. Fusion with alkalis and subsequent determination with mercurous nitrate.

The details of these assays are given in order that the investigations may be followed.

1. Aqua Regia Method.—(All assays by this method are stated in the table under the column headed "Aqua Regia Method.")—Five gm. of the finely powdered sample are digested at the boiling point with 50 cc. of hydrochloric acid for several hours; 10 cc. nitric acid are then added and the digestion continued for one or two hours. The assay is well diluted with water

\*Paper read before the Institution of Mining and Metallurgy, London, May 20, 1909.

and allowed to stand overnight. After filtering and washing, the tungstic acid in the residue is dissolved in dilute ammonia, filtered, and the ammonium tungstate acid obtained from ignition of the ammonium tungstate is evaporated with hydrofluoric acid to remove silica, and again ignited.

2. Aqua Regia Method with Previous Treatment with Hydrofluoric Acid, etc.—(Assays by this method are stated in the table under column headed "Modified Aqua Regia Method.")—Five grm. charges are evaporated with hydrofluoric acid in a platinum dish to dryness, the dried residue is subsequently transferred to a beaker with water giving a volume of about 40 cc. 5 cc. nitric acid is added and the assay gently warmed to remove the bulk of the mispickel. After well diluting and allowing to stand overnight it is filtered and the residue washed on to the paper, dried and burnt. The residue, after powdering again in an agate mortar, is decomposed by aqua regia, etc., as previously described.

Method 3. Determination by Fusion with Alkalis and subsequent Determination with Mercurous Nitrate.—(Assays by this method are stated in the table under column headed "Soda Fusion Method.")—Except for slight alterations of detail, Bollnheimer's method was followed, viz.: The silica and mispickel are removed from a 5 grm. charge as described in the previous method. The residue is again powdered and fused in a nickel dish with caustic soda and sodium peroxide. The melt, when cold, is extracted with water and diluted to 250 cc., of which 200 cc. of a filtered portion are used for the actual assay. The alkaline liquor is acidulated with nitric acid, followed by ammonia, till fairly alkaline, boiled, filtered and washed. The filtrate containing the tungsten is made neutral or faintly acid with nitric acid; mercurous nitrate solution is then added, followed by a little freshly precipitated HgO or a few drops of diluted ammonia. After warming and stirring, the precipitate settles well. It is determined as  $WO_3$  by ignition in a platinum crucible followed by treatment with hydrofluoric acid.

New Method.—Determination by Digestion with Caustic Soda Solution and subsequently by Mercurous Nitrate.—That wolfram is decomposed by boiling or by digestion on a water bath with caustic soda solution was noted in the course of laboratory experiments on wolfram products. Investigations followed to see if the reaction could be adapted to replace the fusion with soda. With a view to its use as a solvent for wolfram in low-grade ores it was desirable first to test it on a wolfram concentrate. A sample of wolfram concentrate (No. 24) was selected which had been agreed upon by buyer and seller—its value was 63.2%  $WO_3$ .

0.4146 grm. of the finely powdered sample was digested with about  $1\frac{1}{2}$  in. stick soda and 15 c.c. of water in a porcelain dish on a water bath for 45 minutes. The assay was diluted with water, a little sodium peroxide added, filtered and washed. The tungstic acid was determined in the filtrate by mercurous nitrate after removal of silica, etc., as in previous methods. The weight of  $WO_3$  obtained was 0.2610 grm.=62.97%  $WO_3$ .

The decomposition of wolfram under such conditions was sufficiently complete to make possible the assay of low values. Mispickel digested with soda solution is only slightly attacked; the effect of arsenic is dealt with later.

Details of the New Method of Assay as used for Low-grade Ores, Tailings, etc. (Assays by this method are stated in the table under column headed "New Method.")—The charge taken may be from 5 grm. upwards, or better 5.6, 11.2, 16.8 or any convenient multiple of 2.8, so that the milligrams of tungstic acid obtained represent simple ratios of lb.  $WO_3$  per ton of ore (long ton). 2.8 grm. (or multiple) is taken because only four-fifths of the solution is used for the actual assay, i.e., it is a convenient sort of "assay ton" for lb. per ton of 2,240 lb. under the special conditions of the assay. The charge is digested in a 4-in. porcelain dish with 20 cc. of a 25% solution of caustic soda (free from chloride) on a water bath for 30 to 45 minutes. The assay is next diluted, a little sodium peroxide added to oxidise any decomposition products of sulphides, then transferred to  $\frac{1}{4}$  litre flask and diluted to 250 cc.; 200 cc. of a filtered portion are first acidified with nitric acid, then made alkaline with ammonia. The assay is brought to the boiling point, filtered and washed. The filtrate is made slightly acid with dilute nitric acid, and mercurous nitrate solution added in excess followed by a few drops of dilute ammonia. On warming and stirring, the precipitate settles readily. After filtering and washing the precipitate with weak mercurous nitrate solution, the paper and precipitate are ignited together in a porcelain crucible, or, if the ore is free from arsenic, in a platinum crucible. Weigh as tungstic acid; with a charge of 5.6 grm., the milligrams obtained, divided by two, give lb.  $WO_3$  per ton.

For assays of ores and tailings the sample may be reduced to a sufficient degree of fineness in a wedgwood mortar, but for concentrates an agate mortar is necessary; fine powdering is essential. 20 cc. of a 25% solution of caustic soda is sufficient to decompose charges containing not more than 0.4 grm. of tungstic acid. The attack with soda is rapid under these conditions; 0.4 grm. of wolfram concentrate being decomposed in 15 minutes to the extent of 98% of its tungsten contents, but, as a rule, from 30 to 45 minutes is given.

Strength of Mercurous Nitrate Solution.—The solution may be conveniently prepared from mercury. From 2 to 3 oz. of mercury is digested in a large beaker or flask, with 25 cc. of nitric acid (sp. gm. 1.4) and 75 cc. of water on a hot plate near boiling point for one and a half hours, and left on the hot plate overnight. The extract, diluted to about 400 cc., will give a saturated solution with the minimum of free acid. 20 cc. is sufficient for most assays.

Where a porcelain crucible has (from the presence of arsenic in the ore) necessarily to be used, it is advisable to burn a batch of precipitates one after the other, and at the end transfer the accumulated tungstic acid to a platinum crucible for treatment with hydrofluoric acid. The loss with hydrofluoric acid is usually very small, e.g., on three assays of mineral from the battery, working with a charge of 5.6 grm., the total loss was 0.5 mg., equivalent to 0.08 lb. per ton on each assay.

In the presence of scheelite the method is not applicable since the mineral is only partly attacked under the conditions of the assay. The effect of varying charge is seen by reference to the results given in the table for samples No. 7, 10, 11, 13 and 23, in the column headed New Method.

In the table are set out assay results, by the various methods, of many kinds of products, including mineral from the battery, intermediate concentrates burnt and unburnt, finished concentrates both of tin and wolfram.

and tailings. The assays are stated in lb. of tungstic acid per ton except for No. 24, where % composition is given. The unreliability of the aqua regia methods is very evident.

### Remarks on Some of the Assays.

Sample No. 7.—The residual gangue from each of the three assays by the aqua regia method and from the one by the modified aqua regia method were tested by the "soda digestion" method (i.e., the new method) for tungstic acid. Since no tungstic acid was obtained the low results were not due to incomplete attack by aqua regia.

Sample No. 10.—In both assays by the ordinary aqua regia method it was impossible to obtain a clear ammoniacal filtrate; the high results were not surprising. The aqua regia filtrates, evaporated to dryness

gram. are not conveniently treated since the fusion introduces large quantities of solids into the assay, and in addition much time is occupied with the very necessary preliminary treatment with hydrofluoric acid.

### Section II.

Determination of the Solubility of  $WO_3$  in Aqua Regia Under Assay Conditions and the Recovery of the Dissolved  $WO_3$  from the Acid Liquors.

The following five charges were weighed out:—

| Experiment.          | I. | II. | III. | IV. | V. |
|----------------------|----|-----|------|-----|----|
| Wolfram, mg. ....    | 80 | 80  | 80   | 80  | 80 |
| Clay, grm. ....      | —  | 2   | 2    | —   | 2  |
| Fluorspar, grm. ...  | —  | —   | 2    | —   | —  |
| Mispickel, grm. .... | —  | —   | —    | 1.5 | —  |

ASSAY RESULTS IN POUNDS OF TUNGSTIC ACID PER TON OF 2240 LB., EXCEPT FOR SAMPLE 24, WHERE PERCENTAGE IS GIVEN.

and tested for tungstic acid, yielded a trace only. From the acid filtrate of the assay by the modified aqua regia method, tungstic acid equivalent to 6 lb. per ton was recovered by evaporation, making a total of 20 lb. The increased solubility of the tungstic acid can only be accounted for by the supposition that fluorides influence the solubility.

The effect of mispickel, or more correctly of arsenic, on the solubility of tungstic acid in aqua regia is seen by reference to the two assays each of samples 14 and 15 in the column headed "Aqua Regia Method."

The assays of samples 11 and 23 indicate the usefulness of the new method in accurately determining exceedingly small values.

The method involving fusion with alkalis and subsequent determination with mercurous nitrate is a very good one, and the results are reliable. It is, however, unsuitable for frequent use; larger quantities than 5

(The tungstic acid in each of experiments I., II., III. and V. was 50 mg.; experiment IV. contained 60 mg., the extra amount being carried by the mispickel added.)

To each 50 cc. of HCl were added and boiled until the decomposition of the wolfram was complete; 10 cc. of nitric acid were then added and digestion continued for 30 minutes more.

The assays were well diluted and allowed to stand overnight. As noted at the time of dilution in experiment I., the  $WO_3$  soon commenced decomposition in a finely divided form, but took a long time to settle; in experiment II., the presence of the clay somewhat masked the appearance, which seemed very much like experiment I., except that it settled quicker; experiment III. settled readily with a clear liquor and no very decided appearance of  $WO_3$  visible most decidedly

less than in experiment I.; experiment V. settled at once with no appearance of  $\text{WO}_3$ .

Their appearance next morning was not very different, except that the assays containing fluorides showed a tendency for  $\text{WO}_3$  to salt out at the surface and in places where a glass rod had touched the sides of the beaker.

Each assay was filtered and washed. The  $\text{WO}_3$  in the residues was determined as usual with  $\text{AmHO}$ , etc.—the weights of  $\text{WO}_3$  obtained being:—

| I.     | II.    | III.   | IV.      | V.      |
|--------|--------|--------|----------|---------|
| 48 mg. | 56 mg. | 20 mg. | 12.4 mg. | 2.4 mg. |

The ammoniacal filtrates in experiments II. and III. were turbid, II. was particularly bad and was not improved by repeated filtration—the  $\text{WO}_3$  obtained even after treatment with hydrofluoric acid was far too white to be accepted as reasonably pure.

Recovery of the dissolved  $\text{WO}_3$ .—The acid filtrates were evaporated to dryness and the residues gently ignited. After dissolving in a mixture of 5 cc.  $\text{HNO}_3$  and 10 cc.  $\text{HCl}$  the solution was well diluted and allowed to stand for 12 hours. By comparison the order of recovery was easily perceptible by eye, but the actual amounts recovered as determined in  $\text{AmHO}$ , etc., were:—

| I.    | II.     | III.     | IV.     | V.       |
|-------|---------|----------|---------|----------|
| 1 mg. | 9.5 mg. | 26.0 mg. | 3.0 mg. | 45.0 mg. |

It is very probable that in experiment I. the  $\text{WO}_3$  obtained was really due to a faint turbidity.

The experiments prove conclusively the effect of fluorides and arsenic on the solubility of  $\text{WO}_3$  in aqua regia. The effect of the former may be eliminated by evaporation, but the effect of the latter is more pronounced and difficult to eliminate.

Attempts were made to recover  $\text{WO}_3$  from arsenical liquors by the following methods, but with only partial success, since lime is rarely absent from ores.

(The only practicable method would seem to involve a fusion of the residues from evaporation of the liquor with sodium carbonate.)

The aqua regia filtrate after evaporation was again taken to dryness with 10 cc.  $\text{HNO}_3$  to expel chlorides. The residue was digested with soda solution for 15 minutes, filtered and washed. The  $\text{WO}_3$  was then determined by mercurous nitrate after removing silica, alumina, etc., by ammonia, and the arsenic by magnesia mixture.

In the assay of sample No. 20 referred to in the table the acid filtrate yielded  $\text{WO}_3$  equivalent to 6.0 lb. per ton by evaporation, and a further amount equivalent to 10 lb. per ton by the method described.

In addition to determining factors which may cause low results in the aqua regia method, the possibility of factors tending to give high results by the "soda digestion," or new method, was recognized and investigated.

The burnt concentrates, in addition to a little unburnt mispickel, always contain small quantities of arsenate, so that arsenates would certainly be present in the soda extract.

The Action of Caustic Soda on Mispickel.—In working the assays by the soda digestion method, a yellow coloured solution was always obtained when mispickel was present, the richer the sample in mispickel the more pronounced being the colour. Dilution and addition of a little sodium peroxide removed the colour, the change being accompanied by a small precipitate of ferric hydrate. In the first instance, in seeking for

evidence of attack of mispickel by soda the alkaline liquors were tested for sulphide with lead acetate and found to be free, but as it is more than probable that iron sulphide would be formed in the first stage of attack the test was not conclusive. Using magnesia mixture, arsenic was detected in the assay liquors, the precipitate of silica, alumina, etc., also carried small quantities of arsenic.

#### Determination of the Amount of Decomposition.

1. Rich Arsenical Concentrates.—The sample used was No. 23 (see description in the table). A 5-grm. charge was digested with soda as in an assay, diluted, treated with peroxide of sodium, filtered and washed. The silica and alumina were removed as customarily and the arsenic in the filtrate obtained, separated by magnesia mixture giving 18 mg. of magnesium pyroarsenate, equivalent to 13.5 mg. of  $\text{As}_2\text{O}_5$ .

2. A Typical Sample of Ore (containing 1.5% As).—4.48 grm. of sample No. 7 (description in the table), treated as in 1., gave 3.5 mg. of pyroarsenate = 2.6 mg. of  $\text{As}_2\text{O}_5$ . The amount of decomposition, though small, could not be ignored, more especially as in weathered ores such as dump samples and old tailings, and also in burnt concentrates, the proportion of arsenic soluble in soda might be considerably more.

#### The Effect of Arsenic in the Mercurous Nitrate Method.

Two solutions were prepared:—

1. A solution of  $\text{As}_2\text{O}_5$  in dilute  $\text{HNO}_3$  strength 1 cc. = 1 mg.  $\text{As}_2\text{O}_5$ .

2. A solution of  $\text{WO}_3$  in dilute ammonia, strength 1 cc. = 1 mg.  $\text{WO}_3$ .

(a) The Behaviour of Mercurous Arsenate on Ignition.—100 cc. of the arsenic solution was (after carefully neutralizing) precipitated with mercurous nitrate; the precipitate after filtering, washing and drying, was detached from the paper and ignited over a Bunsen burner in a porcelain crucible for 10 minutes. The residue, which was still yellow and showing slight signs of fusion, weighed 0.2774 grm. On further ignition over a large burner the product fused and volatilized, leaving a small whitish residue of 2.5 mg. Its appearance suggested corrosion of the crucible.

The experiment was repeated with another 100 cc., but the paper and mercurous arsenate were burnt together; an ignition of five minutes over a moderate Bunsen flame was quite long enough to volatilize the product, leaving a small white infusible residue of 1.8 mg.

40 cc. of the arsenic solution treated in the same manner left a residue of 1 mg.

The presence of the filter paper during the ignition of mercurous arsenate by acting as a reducing agent facilitates its decomposition and volatilization.

100 cc. of the tungstic acid solution treated in like manner yielded .0990 grm.  $\text{WO}_3$ , and .0988 in duplicate.

(b) The Behaviour of Mixed Mercurous Tungstate and Arsenate on Ignition.

|                                                                | I.      | II.     | III.    |
|----------------------------------------------------------------|---------|---------|---------|
| $\text{WO}_3$ solution taken.....                              | 100 cc. | 100 cc. | 100 cc. |
| $\text{As}_2\text{O}_5$ solution taken....                     | 10 cc.  | 50 cc.  | 100 cc. |
| Weight of $\text{WO}_3$ obtained.                              | .0997   | .1005   | .1005   |
| Less correction for residue from $\text{As}_2\text{O}_5$ ..... | .0995   | .0995   | .0987   |

The three experiments, conducted like the previous ones with arsenic, viz., paper and precipitate being

burnt together, show that the effect of arsenic is a negligible factor in products containing 100 lb.  $\text{WO}_3$  per ton or less, even ignoring the correction for the residue obtained from the arsenic solution.

(c) The Separation of  $\text{As}_2\text{O}_5$  from  $\text{WO}_3$  by Magnesia Mixture.

|                                              |           |            |
|----------------------------------------------|-----------|------------|
| $\text{WO}_3$ solution taken .....           | 50 cc.    | 100 cc.    |
| $\text{As}_2\text{O}_5$ solution taken ..... | 20 cc.    | 30 cc.     |
| $\text{WO}_3$ recovered .....                | .030 grm. | .0972 grm. |

In the two experiments IV. and V. the arsenic was removed by magnesia mixture previous to the determination of the  $\text{WO}_3$ .

For experiment IV. the magnesia mixture was made from ordinary calcined magnesia. The loss of .019 grm. of  $\text{WO}_3$  is the effect of lime contained by the magnesia. For experiment V. the magnesia mixture was made from magnesium ribbon.

As to whether the separation of  $\text{As}_2\text{O}_5$  from  $\text{WO}_3$  is actually attended with a slight loss of the latter the authors do not feel justified in stating an opinion; further investigation was discontinued.

**The Effect of Arsenic Added in the Form of Mispickel.**

(d) 2.24 grm. of the sample 23 (see description in the table) were digested with soda, diluted, treated with peroxide, and filtered into 100 cc. of the ammonium tungstate solution. By so doing the conditions of an actual assay were obtained with freedom from sampling error. The joint liquors assayed for  $\text{WO}_3$  without removing the arsenic give: .1010 grm.  $\text{WO}_3$ , subject to a deduction of 1 milligram for  $\text{WO}_3$  contained by the 2.24 grm. charge of sample No. 23.

(e) Ore No. 10 with a charge of 5.6 grm. and 4.5 grm. of mispickel added assayed, without the removal of arsenic, 22.4 lb.

(f) 1.25 grm. wolfram concentrates (refer to Table No. 24) was digested for 75 minutes with 7.5 grm. caustic soda dissolved in 20 cc. water. The extract was treated with a little peroxide, diluted to 250 cc. and filtered. Two portions of 100 cc. each of the filtrate were assayed for tungstic acid by precipitation with  $\text{HgNO}_3$ , to one portion 25 cc. of the arsenic acid solu-

tion were previously added, to the other no arsenic. 0.3180 grm. of  $\text{WO}_3$  was obtained from the former, 0.3162 grm. from the latter, the percentage of  $\text{WO}_3$  being 63.6 and 63.2% respectively.

#### General Remarks.

The authors have found the new method exceedingly useful for assays of battery pulp and tailings. The records obtained over a long period are such as to enable the wolfram losses to be apportioned to the respective products with a degree of accuracy hitherto unattainable. The comparison of losses when crushing to different sizes is not only possible, but has been attempted with success. Screening tests, whether of battery pulp or tailings, may be attempted with confidence. An example of the method on a sample of tailings is given:—

A charge of 11.2 grm. was used for each of the assays.

By direct assay the sample gave 4.75 lb.  $\text{WO}_3$  per ton. The slime was separated from the sand by decantation with water and the sand separated into two portions with a 60 sieve. The three products were then assayed for  $\text{WO}_3$ .

#### Screening Test of Tailings.

| Description.         | % by Weight | Assay Value.                          |
|----------------------|-------------|---------------------------------------|
| Left on 60 sieve ..  | 22.6        | 0.5 lb. $\text{WO}_3$ per ton.        |
| Passed 60 sieve .... | 53.8        | 4.0 " " " " }                         |
| Slimes .....         | 23.6        | 11.7 " " " " } Average 5 lb. per ton. |

For work of this kind the new method is not only more accurate, but is speedier than any other method.

The method is applicable to most wolfram ores; there may be some ores where the presence of particular minerals may necessitate modifications of the assay.

In conclusion it has been brought to the authors' notice that the use of caustic soda has been patented as a process for the production of tungstate of soda from wolfram; the investigations were conducted quite independently.

## THE COVINGTON COKE DRAWING AND LOADING MACHINES.

It is a curious fact that human inventiveness has stopped short in several industries. With strangely universal apathy, certain devices and methods that should have been obsolete fifty years ago, yet form integral parts of modern metallurgical plants.

One survival is the stamp mill. Admirable as is the equipment of modern gold mills, no one can contend that the stamp mill is an efficient mechanical contrivance. It is an inheritance from the middle ages. Other instances could be quoted. But the most glaringly wasteful of all is the bee-hive coke oven, for the operation of which a totally disproportionate amount of manual labor is necessary. Moreover, the loss in heat-energy and by-products amounts to from 30 per cent. to 50 per cent.

That such patent and prodigal wastefulness has survived so long is astonishing. One reason is, of course,

the light initial cost of the bee-hive as compared with by-product ovens. The natural antipathy of old-fashioned operators to change, is another. Both are insufficient to justify the unprofitable employment of men when a machine can do the work with far greater efficiency and despatch.

There is now installed at the plant of the Atikokan Iron Co., Port Arthur, Ont., a coke drawing and loading machine that is revolutionizing the operation and construction of coke ovens. Its effect upon operating expenses is clear when it is stated that with it two men can draw and load into cars the coke from 30 to 40 ovens per day, thus doing the work of from 10 to 13 men. In the construction of new ovenyards the machine makes it unnecessary to include expensive yard walls, fills, and cuts, as it delivers the coke into the cars on a level siding.

696-2

Diagram of Boom & Yard  
for  
Atikokan Iron Co., Ltd.  
Covington Machine Co  
Covington, Va.

June 1, 1909

| Number   | Hand  | Our       | Atikokan Iron  | Line     | Length of | Volage | Style of  |
|----------|-------|-----------|----------------|----------|-----------|--------|-----------|
| Machines |       | Order No. | Order No.      | Ordn.    | Railroad  |        | Machine   |
| 1        | L. H. | 545       | Letter No. 230 | Straight | 23'-0"    | 250    | 1909 Type |

To-day, in the Pennsylvania coke regions there are over 120 of these machines, the Covington coke drawing and loading machines, installed. More than 4,000 ovens are served. The manufacturers are the Covington Machine Company, Covington, Virginia.

The accompanying half-tone shows the machine in operation. The diagram shows a cross section of the Atikokan yard as arranged for the machine.

The 1909 Covington machine is an improvement on its predecessors. The conveyor and drive-chains are of manganese steel. All important gears are of cast steel, and bronze bushings have supplanted cast iron in all bearings.

As now constructed the machine requires only a distance of 27 inches from the line of the bottom of the oven to the line of the top of the machine track, as

against 41 inches required by earlier models. Little or no grading is required.

The ram-carriage is now moved by a small motor, thus doing away with the arduous manual labor required by the hand-wheel and screw of former models.

One operator can easily handle the machine all day long.

The extractor and conveyor trucks may be uncoupled thus allowing the extractor to move up and down the track while drawing the oven, the conveyor remaining stationary and depositing the coke at one point in the car.

Altogether the Covington machine, inasmuch as it does away with distressingly arduous manual labor, and saves money in erection and operation of ovens, is an innovation that should be welcomed in Canada.

## Note on the Determination of Carbon and Phosphorus in Steel.\*†

By Andrew A. Blair, Philadelphia, U.S.A.

It will be remembered that in the last paragraph of the joint report on "Comparison of Methods for the Determination of Carbon and Phosphorus in Steel," by Baron H. Juptner von Jonstorff (Austria); Andrew A. Blair (United States); Gunnar Dillner (Sweden); and J. E. Stead, F.R.S., Member of Council (England), it was stated that "the committee are continuing their investigations, and are endeavouring to ascertain whether or not hydrocarbon gases do escape when steel is dissolved in cupric potassium chloride, and the reason for the discrepancies shown above, the results of which will be presented on some future occasion."

On October 23, 1906, the following results were sent to Mr. J. E. Stead, and were reserved by him in the hope that other communications would be forthcoming from the other members of the committee. As I am given to understand that no such communications have been received, I suggested that my report should be presented independently at the May meeting, 1909.

In accordance with the programme suggested by Mr. Stead, I have made the following experiments, having previously obtained supplies of drillings of No. 1 and No. 4 International Standard Steels as prepared for the use of the International Committee and of the "Special Arsenic Standard" prepared for the American Committee.

The advantages to be gained by the use of these steels in an investigation of this character is apparent.

The analysis of these steels is as follows:—

### No. 1 International Standard.

|                     | English<br>Committee.<br>Per cent. | Swedish<br>Committee.<br>Per cent. | American<br>Committee.<br>Per cent. |
|---------------------|------------------------------------|------------------------------------|-------------------------------------|
| Carbon . . . . .    | 1.414                              | 1.450                              | 1.440                               |
| Silicon . . . . .   | 0.263                              | 0.257                              | 0.270                               |
| Sulphur . . . . .   | 0.006                              | 0.008                              | 0.004                               |
| Phosphorus . . . .  | 0.018                              | 0.022                              | 0.016                               |

| Phosphorus . . . . . | 0.078                              | 0.102                              | 0.088                               |
| Manganese . . . . .  | 0.130                              | 0.130                              | 0.098                               |

### Special Arsenic Standard.

|                      | Full<br>Analysis.<br>Per Ct. | Determinations of Phosphorus. |                       |
|----------------------|------------------------------|-------------------------------|-----------------------|
|                      |                              | Analyst                       | Phosphorus<br>Per Ct. |
| Carbon . . . . .     | 0.466                        |                               |                       |
| Phosphorus . . . . . | 0.098                        |                               |                       |
| Manganese . . . . .  | 0.720                        | P. W. Shimer                  | 0.098                 |
| Sulphur . . . . .    | 0.043                        | C. B. Dudley                  | 0.099                 |
| Silicon . . . . .    | 0.296                        | T. M. Brown                   | 0.104                 |
| Copper . . . . .     | 0.056                        | A. A. Blair                   | 0.098                 |
| Arsenic . . . . .    | 0.185                        | W. P. Barba                   | 0.095                 |

In composition these steels vary sufficiently to cover practically all classes of ordinary carbon steels, and the results obtained should furnish evidence of the accuracy of the different methods used, taking for granted the skill of the analyst and the care exercised by him in carrying out the work.

### Determination of Phosphorus.

By the regular method for phosphorus adopted by Sub-Committee on Standards of American International Steel Standards Committee, and described in the Journal of the Iron and Steel Institute, 1904, No. I. p. 239:—

Phosphorus.  
Per cent.

|                                    |       |
|------------------------------------|-------|
| No. 1 Standard . . . . .           | 0.016 |
| No. 4 Standard . . . . .           | 0.088 |
| Special Arsenic Standard . . . . . | 0.098 |

By the Eggertz method 2 grammes of steel used.

The precipitate of ammonium phosphomolybdate was filtered on an asbestos felt in a Gooch crucible, washed with water and molybdate (1—1), then with 1

\*Supplement to the Report presented in October, 1904. Journal of the Iron and Steel Institute, 1904, No. 11, pp. 221-273.

†Paper read before the Iron and Steel Institute, London, May, 1909.

per cent. nitric acid, and dried for two hours at 110° C. and weighed. The precipitate was then dissolved in dilute ammonia acidulated with sulphuric acid, reduced and nitrated as in the first method:—

|                               | Weight of<br>Ammonium<br>Phospho-<br>molybdate. | Phosphorus<br>(factor<br>0.153). | Phosphorus<br>by<br>Titration. |
|-------------------------------|-------------------------------------------------|----------------------------------|--------------------------------|
| No. 1 International Standard. | 0.0210                                          | 0.017                            | 0.017                          |
| No. 4 International Standard. | 0.1046                                          | 0.085                            | 0.085                          |
| Special Arsenic Standard..    | 0.1273                                          | 0.104                            | 0.104                          |

I have made many determinations in other steels by these two methods, and the results agree very closely in all cases. In the committee's methods the results are obtained in much less time and with less labour than in the Eggertz method. The question of weighing the precipitate of phosphomolybdate or of dissolving, reducing, and titrating it, seems to be largely a matter of custom or personal preference. I believe the titration method to be the more rapid of the two, and I use it continually with perfect satisfaction and confidence.

#### Determination of Carbon.

The suggestion of Baron Juptner that hydrocarbons are evolved when steel is acted on by ammonium or potassium cupric chloride seems reasonable, and the facts in regard to it should be determined positively.

In addition to the two International Standards, there was prepared for me by the Midvale Steel Company of Philadelphia (for whose kindness in this matter I wish to make suitable acknowledgment) a sample of steel containing about 1.2 per cent. carbon, one bar annealed at 550° C., one annealed in lime, and one hardened.

These samples were all treated as follows: A factor weight (2.7276 grammes) was introduced into a 400 cubic centimetre Erlenmeyer flask fitted with a stopper carrying two tubes, one reaching to the bottom of the flask and connecting with the supply of properly purified oxygen and air, and the other beginning just below the stopper and connecting with a copper tube filled with oxide of copper. The copper tube passed through a gas furnace and was heated to a bright red. The copper tube was connected with an ordinary purifying train consisting of a U tube filled, one end with anhydrous cupric sulphate and the other with solid cuprous chloride, and a second U tube filled with dried calcium chloride. To this purifying train was attached an absorption apparatus consisting of a Liebig bulb containing potassium hydrate and a drying tube containing dried calcium chloride. A guard tube containing calcium chloride completed the train. The absorption apparatus was weighed, the entire train connected, and 200 cubic centimetres of the potassium cupric chloride introduced into the Erlenmeyer flask. A current of purified oxygen was passed through the apparatus until the steel and the deposited copper were dissolved, when air was substituted for the oxygen. The absorption apparatus was then weighed. The current of oxygen passing through the liquid in the Erlenmeyer flask carried forward any gases generated by the action of the copper salt on the steel, and complete oxidation was insured by the red-hot oxide of copper in the tube. It was found that the deposited copper had a tendency to cement the steel drillings into a compact mass very difficult to dissolve in the

excess of copper salt. This was overcome by mixing the drillings with coarse ignited quartz sand, so that, aided by an occasional shaking of the flask and the gradual heating of the solution by the radiant heat from the furnace, complete solution was effected in about two hours.

The residue on the flask was filtered on an asbestos felt in a platinum boat and burned in the regular way in a platinum tube in a current of oxygen. The result served as a check on the work. When the neutral copper salt was used there was always a heavy deposit of basic ferric chloride or ferric oxide in the solution, and at the end of the operation it was necessary to introduce into the Erlenmeyer flask about 30 or 40 cubic centimetres of hydrochloric acid 1.1 specific gravity to dissolve it. This was generally done when air was substituted for the oxygen.

The determinations were checked by direct combustion of the drillings in a platinum boat, partly filled with ignited alumina, in a platinum tube in a current of oxygen. The tube was heated to intense redness, and the operation was conducted exactly as described on p. 134 of the sixth edition of the "Chemical Analysis of Iron," and by solution of the drillings in acid potassium cupric chloride, filtration and combustion of the residue in oxygen. The results are shown in the following tabulated statement:—

| Direct combustion of drillings.....                                                 | 1.280                |
| Solution in acid potassium cupric chloride and combustion of residue .....          | 1.267                |

These samples were all ordinary carbon steels, but as experience has shown me that on chrome-tungsten steels the direct combustion method gave much higher results than the combustion of the residue from treatment with potassium cupric chloride, a high chrome-tungsten steel was treated with the following result:—

|                                                                                  | Carbon.<br>Per cent. |
|----------------------------------------------------------------------------------|----------------------|
| Combustion of evolved gases from acid solution of potassium cupric chloride..... | 0.002                |
| Combustion of residue from flask .....                                           | 0.543                |
| Direct combustion of drillings.....                                              | 0.692                |
| Solution in acid potassium cupric chloride and combustion of residue .....       | 0.567                |

The results of these experiments lead me to the conclusion that the opinion I expressed in 1891,\* that there was no evolution of hydrocarbons when steel was treated with a copper salt, was absolutely correct. There is abundant evidence to show that, as I then stated, there is a "solution of the carbonaceous matter by the alkaline salts in the absence of an excess of acid," which is not precipitated by the subsequent addition of acid. The agreement in the results obtained by the direct combustion process and the combustion of the residue from the solution of the steel in acid potassium cupric chloride is so very close that I think that either method may be considered capable of yielding correct results. I now use the direct combustion method practically to the exclusion of all others, because it requires less work, and the results can be obtained in a shorter length of time. I am, therefore, in this conclusion heartily in accord with Mr. Stead; but by using a platinum tube I find no difficulty in obtaining correct results, no matter how thick the drillings may be, for I have made a number of determinations by burning coarse drillings directly and breaking up portions of the same lot of drillings until they passed through a fine sieve and then burning them, obtaining results rarely differing more than 0.005 per cent.

\*In this case the absorption apparatus lost weight.

\*Journal of Analytical and Applied Chemistry, vol. 4, p. 121.

I made several determinations by the Swedish direct combustion method, but did not obtain results sufficiently accurate to repay me for the trouble and work involved. Perhaps if I had had more time, or if I had been forced to use this process because the others were not available, I might have been more successful. Mr. Dillner's assertion that the direct combustion method is not suitable for pig irons does not accord with my experience. By mixing the sample of pig iron with an equal weight of low carbon steel or electrolytic iron, I have had no difficulty in getting results that agreed perfectly with those obtained by solution in potassium cupric chloride and combustion of the residue. This is equally true in regard to ferro-chrome and all other iron or steel alloys with which I have had experience.

The secret of success in this process is the rapid heating and combustion of the steel, for the heat furnished by the oxidation of the metal is sufficient not only thoroughly to oxidize the material, but to melt the resulting oxide into globules. It occasionally happens that the melted oxide runs through the bed of alumina and fuses to the bottom of the boat, to which it adheres so closely that it can be detached only by melting potassium bisulphate for a long time in the boat. The thin platinum cover which I use to prevent the spattering of the oxide on the inside of the tube is frequently perforated by the fused material.

The method is used in several large steel works, where one operator with four tubes makes as many as forty combustions in a day.

I have been informed by Mr. Stead that his results and researches fully confirm the fact that there is no evolution of hydrocarbons when steel is treated with copper salt in the manner described in the original report, and that later investigations have proved that the direct combustion method is par excellence the best and most accurate for the determination of carbon in steel.

## PERSONAL AND GENERAL.

Mr. O. N. Scott has returned from a professional visit to Madoc, Hastings County, Ont.

Mr. Elias Rogers, president of the Crow's Nest Pass Coal Company, is to visit British Columbia early in July.

Dr. A. E. Barlow, who is superintending prospecting and development operations on the claims of the Miller Lake syndicate, Miller Lake, is ill in Montreal.

Mr. F. H. Sexton, director of Technical Education, Halifax, N.S., was in Toronto early in June. Mr. Sexton is travelling in the interests of the new Technical College.

Mr. C. J. Tompkins, late of the Accounting Department of the Dominion Coal Company, has been appointed Secretary-Treasurer of the Imperial Coal Company, Frank, Alta.

Messrs. Burr & Fergusson, civil, hydraulic and mining engineers, announce that they have opened offices in suite 216-217, Loo Building, corner Hastings and Abbott streets, Vancouver, B.C.

Mr. R. G. Edwards Leckie returned on June 18th from a visit to Vancouver. He is now on his way back to British Columbia to spend some time in looking over mining properties in that province.

"*Sic Semper Tyrannis*. The engagement is announced of Miss Frances Muriel Cronyn to Mr. H. E. T. Haultain, son of the late Major-General Haultain. The wedding will take place in September.

At a meeting of the Lake Superior Corporation held in New York on June 11, Mr. Charles D. Warren, of Toronto, was elected president and Mr. T. J. Drummond, of Montreal, second vice-president.

Mr. E. S. Moore, formerly identified with the Ontario Bureau of Mines, has taken his Ph.D., *summa cum laude*, at the University of Chicago. He has accepted the appointment of Professor in Geology in the Pennsylvania State College.

Mr. R. B. McKay, who graduated from the School of Mining, Kingston, in 1904, is visiting Cobalt. For the past five years Mr. McKay has been engaged in contract mine surveying in the gold camps of British Columbia and Nevada. He is now making Cobalt his temporary headquarters.

Mr. Angus W. MacDonald, who for the past two years has filled the position of employment agent for the Dominion Coal Company, has been appointed general superintendent of the Dominion Coal Company, at Lethbridge, Alta. He will assume his official duties on the 1st of July.

The resignation of Mr. J. Obalski from the position of Superintendent of Mines for the Province of Quebec, has just been announced. Mr. Obalski will take up private practice with headquarters in Montreal. His numerous friends throughout Canada will wish him continued prosperity. For many years Mr. Obalski has been a prominent and useful member of the Canadian Mining Institute and he was this year elected vice-president.

Dr. Henry M. Ami, after 28 years of continuous and faithful service on the staff of the Geological Survey of Canada, retires on July 1. Dr. Ami's health has not been as satisfactory of late as his friends would wish, and his physician has advised him to discontinue his regular duties. Dr. Ami's early training was received at Ottawa. At McGill University he studied for four years under Sir William Dawson. Since his graduation he has been identified with the Geological Survey. His work has received recognition from foreign scientific bodies. He is a fellow of the Geological Society of London, and of similar bodies in Switzerland and the United States.

Members of the Canadian Mining Institute who were able to be present at the Montreal meeting last March, will remember with unmixed pleasure the several talks given by Dr. A. C. Lane, State Geologist of Michigan. The whimsical humor that tinged many of Dr. Lane's utterances was thrown into relief by an undercurrent of practical seriousness and sane idealism. Like Dr. Kemp, he used his wit not wantonly but well. It has just been announced that Dr. Lane is to leave the Michigan Geological Survey. He has accepted an appointment at Tufts College, where, naturally, a wider sphere of work will be assured. Dr. Lane's name, however, will always be associated with the geology of the Lake Superior region. He is, and has been, one of that thoughtful school of geologists who succeed in connecting geology with mining. We wish him all success in his new appointment.

## Correspondence.

Editor Canadian Mining Journal:

Sir,—Your special correspondent from Glace Bay in your issue of May 15th, in his elaborate defence of the Dominion Coal Company's hostility to reciprocity in coal, bears the earmarks of being official and authoritative, and his production, therefore, may be considered as presenting the most favourable view of the company's course of procedure.

The writer summons Hon. Robert Drummond to his aid, and quotes that gentleman's latest revised opinion that Cape Breton coal cannot compete with West Virginia in New England, and he fortifies his opinion by declaring that "Mr. Drummond knows what he is talking about when on the subject of coal." Would "Glace Bay" guarantee that Mr. Drummond knew what he was talking about when he used to assert directly the contrary of what he now states? Was his education incomplete when he formerly extolled reciprocity as the salvation of the Nova Scotia trade, and did he only graduate as a coal expert when he fell under the tuition of the Dominion Coal Company?

Mr. Drummond is expected to be somewhat responsible for his utterances in the Legislative Council. In his speech on 29th March, 1893, when the Whitney Syndicate matter was up, Mr. Drummond argued strenuously (1) there could be no coal combine, (2) there could be no material increase in prices, (3) that Nova Scotia could retain the Quebec market in spite of the remission of duties, and finally, (4) "with the duty removed there would be no trouble whatever in sending coal into the United States market." His opinion was so strong on that point that he even hazarded the opinion that if there were facilities for receiving it "we could send it now in spite of the duty."

Can Mr. Drummond now turn around and convince us that all he has written and spoken about coal markets until a recent date is balderdash and humbug? To-day he ridicules those who believe in an open market as "credulous or deceitful." It is fair to ask which was he during the many years when he promulgated the doctrine of reciprocity? "Glace Bay" quotes him as stating: "At the present time West Virginia coal is selling f.o.b. Boston at \$2.30 per ton, and on cars at \$3.00." Such figures have no basis of fact whatever. The Coal Trade Journal, of New York, on 12th May (page 364) quotes coal at Mystic at \$3.15 and upwards for spot business, and New River and Pocahontas on cars at a higher rate. On the 19th, the same excellent authority says: "George's Creek operators are hard hit, the same as the Pennsylvania operators, but they are maintaining prices fairly well on a basis of \$3.35 to \$3.50 in cars at Mystic. . . . Some of the larger shippers continue to maintain a price on the basis of \$2.50 f.o.b. shipping point." Thus the Trade Journal pretty effectually disposes of Mr. Drummond's quotations. For a number of years the Dominion Coal Company supplied the Boston and Maine Railway at Boston with steam coal at \$2.80 against 67 cents duty. Compare the net price (\$2.13) with the present low prices there, which make a margin of at least one dollar per ton in favor of Cape Breton coal, and a larger margin when brisk times give an upward tendency in prices.

The grand objection of the Dominion Coal Company to reciprocity is the alleged lack of discharging facilities in New England and the necessity of creating them. "Glace Bay" demands: "Would any sane Board of Directors be justified in expending huge sums . . . to

provide costly discharging facilities?" From which we are left to infer that the coal people in New England are behind the times, and still hoist coal with a tub, block and pulley! I do not think it would surprise "Glace Bay" a bit to be informed that some of the best coal-discharging plants in the world are to be found in New England, because the Dominion Coal Company is constantly using some of them. There is no danger that the American coal operators will shut out Cape Breton coal from their use, because, except in one instance, they are not owned by the operators at all, but by local dealers, who always welcome healthy competition, which is said to be the life of trade. Thus the huge bugbear to reciprocity raised by the officials of the Coal Company vanishes into thin air!

"Glace Bay" asks us to believe that the Dominion Coal Company is a benevolent institution operated in the public welfare. He asserts it "is a beneficent business enterprise that has greatly increased the prosperity of the country; . . . that the incorporation of that company was the inception of the greatest impetus ever given to the Maritime Provinces." "Jumping" the price of coal up (say 50 per cent.) is doubtless an instance of the "beneficent" policy of the company to promote the public prosperity and welfare! The jump in price is fully endorsed and justified by "Glace Bay," who admonishes me to learn that it is proper and right to salt the home market, in the advice that I should "take an elementary course in the law of trade and learn how it is that Canadian cheese and Nova Scotia apples can be purchased for less in London than in Sydney."

A knowledge of trade seems not so much lacking as an appreciation somewhere else of sound business morals. If the coal and other minerals of the province are owned by our people, they ought to be operated more in their interests than in the interests of outside communities. If, however, corporations and combines have succeeded in ousting them from their heritage and can defy them, they might as well submit and pay the tribute that brigands in all ages have demanded.

This province wants cheap coal for home consumption. What benefit is it to mine cheap coal for outside communities? If an expansion of the coal trade from two to five millions of tons means dear coal at home and cheap abroad, the less our people have of it the better. If our coal fields are a provincial asset destined to impoverish our people in order to increase the wealth and prosperity of others, our coal mines had better be closed.

To skin home consumers of coal to the limit and call it "beneficent" is a variety of benevolence worthy of Dick Turpin, who, "going through" the hapless wayfarer, bids him to kindly remember him for sparing his life.

The collapse of the Dominion Iron and Steel Company would have been an enormous misfortune to thousands of people financially interested, yet that was the "beneficent" result aimed at by the Coal Company when it refused to supply that company with coal at any price, and then, when forced to renew the supply, raised the price from \$1.28 to \$3.05!

Hon. Mr. Drummond, "who knows what he is talking about," etc., did not, before his conversion, view

the "jump" in prices as a beneficent act. He wrote on 26th May, 1905:—

"I have all along since 1901 maintained that the operators made a great mistake in so largely increasing the price to coal consumers. . . . The operators jumped the price too much and too quickly."

"Glace Bay" quite correctly sets forth the conditions of mining by the Dominion Coal Company, which he alleges "cannot be excelled on this continent. . . . It possesses what is probably one of the most valuable bituminous coal deposits in the world, and has a plant which always astonishes visiting engineers by reason of its completeness and extent."

Why, then, fear West Virginia coal in neutral markets?

I ask of what commercial value is any industry that cannot stand alone—that requires to be bolstered up by protective duties to give it a high-priced market? Why should "one of the most valuable coal deposits in the world" fear competition in its own home market against rivals handicapped by hundreds of miles of inland rail carriage? Why should the earnings of other industrial classes have to come to its aid to keep it alive?

The capital of the company is \$23,000,000, consisting of \$5,000,000 of 5 per cent. bonds, \$3,000,000 of preferred stock and \$15,000,000 of common stock. The latter was originally issued as a sort of bonus, so that the real capital is \$8,000,000, the interest on which is \$460,000 per annum. The average annual net earnings of the company may be set down briefly as \$1,800,000, which is about 23 per cent. on the capital originally invested. About two-thirds of this enormous income, deducting interest, is wrung from the people of Nova Scotia. The Coal Company's employees number about 5,200, only 2,600 of whom are skilled miners. To keep these employed at good wages Dominion Coal advocates allege that high prices for coal are necessary. Assuming that the people of the province pay only \$520,000 above their legitimate coal bill—and it is much more—the other classes in the community, the farmers, lumbermen, fishermen, gold miners, mechanics, etc., are paying \$100 per head of the employees to sustain the coal industry, over and above what they paid previously to 1900! Does this enormous sum reach men in the coal pits? Not a cent of it. The company puts its coal on the cars for about \$1.20 per ton. This includes all labor bills. The miner receives not one cent more whether sales are made at \$1.28 per ton or for \$3.05 per ton. It is all the same to him. Therefore the high prices extorted by the combine on the plea of wages is pure charlatanism.

W. C. MILNER,  
Secretary Free Coal League.

May 31st.

## SPECIAL CORRESPONDENCE

## NOVA SCOTIA.

## Glace Bay, N.S., 18th June, 1909.—Exhaust Steam Turbines.

—What will be, we believe, the first exhaust steam turbine engine in Canada is shortly to be erected in the Central Electric Power House of the Dominion Coal Company at Glace Bay. For several years past exhaust-steam turbines have been in successful use on the continent of Europe, and they have come into especial prominence in colliery work in the Westphalian coal-field of Germany. In recent years it has been found possible to introduce very great economies in boiler-coal consumption at collieries, and one does not often find to-day that the best coal goes to the fires, as too often it used to do in the old days. Nevertheless the peculiar nature of colliery power demands have not conduced to the most economical use of steam, particularly in the case of large hoisting engines, and the modern exhaust-steam turbine seems particularly adapted to meet such conditions. At the present time many of the collieries in England and Scotland are installing turbo-condenser plants and their future extended use seems assured.

The plant to be installed at Glace Bay will consist of one 1,000 k.w. generating unit. The turbine will be of the Rateau design, impulse type, and will utilize exhaust-steam at about atmospheric pressure, or 15 lbs. absolute. It is not yet decided whether the condensers will be jet condensers or barometric type. The circulating water will be taken from a large natural reservoir adjoining No. 2 Colliery. The single generating unit referred to will not utilize the whole of the exhaust steam which

No. 12 Bankhead, Dominion Coal Co., Glace Bay, N.S.

is available at No. 2 Colliery, and if the projected plant proves economical it is expected that another unit will be added.

The current generated will be conveyed by high tension transmission line to the group of new collieries now in course of development in the Lingan-Victoria District. The course of the pole-line will be across Lingan Bar, and the line generally will be very substantially built in order to withstand the high winds which sweep across this Bar in the winter time. The current will be stepped-up to 20,000 volts, and delivered at the collieries at this voltage. The distance from the generating station to the Lingan collieries is about nine miles.

The power at No. 12 Colliery, which is the first of the new group, will be largely steam, but at the other collieries it is expected that all the auxiliary surface engines, such as screen-engines, fan-engines, etc., will be electrically driven. It is also intended to deal with the mine water by means of electrically driven pumps, and the current will be taken underground through transmission boreholes as is the practice at the existing collieries. For the present, at any rate, the haulage will be driven by steam-power. Whether electrically driven haulages will be installed later will depend on the local conditions as they develop, but a certain amount of auxiliary, steam-power will have to be provided at these collieries, or otherwise they would be too entirely dependent on the transmission line.

So far as we are aware no use has as yet been made in this country of small electrically-driven rotary air compressors

operated underground by transmission lines from the surface. Where electric current can be transmitted through boreholes of a convenient depth this is an economical method of driving coal-cutting machinery, as it saves the expensive compressed-air mains which are otherwise necessary, and it further avoids the necessity of taking electric current into the coal face.

**The U.S. Senate and Nova Scotian Coal.**—The Washington Congressional Record of June 8th contains a speech of the Hon Stephen B. Elkins, Senator for West Virginia, during the debate on tariff rates on coal and petroleum which took place on the 2nd of June. Following are some of the "facts" which Senator Elkins told the Senate about Nova Scotian coal, which we cannot do better than quote as they were spoken: "Nova Scotia," said the Senator for West Virginia, "has about a thousand miles square of coal, containing four veins of coal whose average thickness is about ten feet, making about six thousand million tons of coal, two-thirds of which is as good as West Virginia coal." It would be interesting to know where this valuable coal deposit is situated in Nova Scotia. The particulars given do not agree with any coalfield we have ever heard of in this Province, except the remarkable areas which are controlled by Dr. Hugo von Hagen. We have often wondered where the coal was coming from to fulfil that five million ton contract which the shareholders of the Great Northern Coal Company were told had been closed for delivery in 1909. It is quite evident that there must be a coalfield in Nova Scotia known to certain persons in the United States which our Canadian Geological Survey has completely overlooked.

Senator Elkins gives a tabular statement of analyses of various coal seams said to be worked by the Dominion Coal Company. They make a surprising list, being as follows:

|               |               |
|---------------|---------------|
| Victoria      | Gowrie        |
| Springhill    | Caledonia     |
| Acadia        | Reserve       |
| Intercolonial | Lingan        |
| Reserve       | International |
| Nova Scotia   | Gardner       |

We always knew the Dominion Coal Company had a fine property containing numerous seams, but it may be news to the shareholders of this company to know how extensive their property really is.

What is really the most astonishing part of this extraordinary speech was Senator Elkins' assertion that the U.S. Government had been defrauded to the extent of \$1,000,000 of duties caused by evasion of the law by the Nova Scotian operators. The Senator stated "most of the coal imported as slack (from Nova Scotia) was ordinary coal, and should have paid a duty of 67 cents instead of 15 cents. . . . To make this slack question clearer I will go more into detail. It seems that in loading the Nova Scotia coal after it was mined into the railway cars it was dropped from an unusual height. This broke up the coal considerably. Then in unloading it into the boats taking it to Boston it was passed through a tube 60 feet long, with breakers. This also broke up the coal, so that by the time it reached Boston it would nearly all pass through a half-inch screen, and therefore most of it was sent down as slack by the Custom House officer and paid only 15 cents a ton duty. Most of all these importations were made by the New England Gas Company, which has 40 bye-product coke ovens near Boston, and the finer the coal the better it is suited for making coke so this company not only got its coal in on a 15-cent duty but it was prepared just to suit its purpose.

This extract is worthy of the Secretary of the Free Coal League at his best. The reference to the "tube 60 feet long, with breakers" rather puzzles us. We gather that someone has been amusing himself at the Senator's expense. Perhaps, however, the reference is to the Robins belt-conveyor at Louisbourg Pier which is used to load slack coal into vessels. This conveyor is about 600 feet long, and is used to take coal from the slack pocket to the hatch, and has a loading capacity of 700 tons per hour.

The facts of the case are these: The Dominion Coal Company has a contract with the New England Gas Company to supply slack coal for use in the coke ovens at Everett. This coal is all slack that is taken from under the screens in the ordinary process of screening, and it is only because of the fact that it is slack coal that the Dominion Coal Company has not sent a pound of round coal to the New England States since the spring of 1906, nor are they likely to.

Senator Elkins gives some figures to show the great importance of the coal industry of the United States, which we quote and take them as correct, for it is but reasonable to suppose that his figures with regard to the United States will be accurate, notwithstanding the fairy tale about Nova Scotia with which the Senate was amused. In 1908—a dull year—the coal production was 419,000,000 tons, worth \$500,000,000 at the mouth of the mine. If the money involved in transportation be added the sum involved in this great industry is \$800,000,000, and three million people depend upon it directly for a living. Then the Senator speaks of the production of Nova Scotia as being 5,800,000 tons per annum, and states in another part of his speech that with her present development Nova Scotia cannot supply much more coal than she now does. After this statement the Senator gets off the following doleful prophecy: "There are Americans and Canadians waiting to see if coal is put on the free list to buy coal lands in Canada, and if they should, and open new mines, they will ultimately take the New England market, I think, except for the very best quality of coal, and in a few years take all the New England market. The result of this would be so disastrous, so ruinous, and demoralizing to West Virginia, Maryland, and Eastern Pennsylvania, that these states can never consent to the lowering of duty on coal." Truly the United States must be in a parlous condition. The entire Canadian coal production to-day is ten million tons per annum, or expressed as a fraction it is one forty-one-millionth of that of the United States, and if reciprocity in coal should have occurred the result to the States will we are told be 'disastrous, ruinous and demoralizing!' How very consistent!

If Canadian coal lands appreciate in value and contents as we have known them to do when bought by certain American citizens we do not wonder that Canadian competition looms so large in the eyes of the Senators. The prospectus of the Great Northern Coal Company read as follows, in part: "The property owned by this company is very valuable. It consists of three square miles in the heart of Cumberland County, which is famous as the largest coal district in Nova Scotia. Each square mile contains about 37,000,000 tons of coal, or in all about one hundred and eleven million tons (111,000,000 tons). Figuring this coal at 11 cents per ton, which is the value given coal in the ground, gives this property a cash value of \$12,200,000. Twelve million two hundred thousand dollars. Think of it! This means that every share of stock has nearly \$500 back of it. It means that the Company will be mining coal when our grandchildren are married one hundred or two hundred years from now." This is the description of a certain Nova Scotian coal property by a gentleman who advertises as Henry N. Roach, 373 Fifth Avenue, New York, and who publishes a weekly newspaper known as "Roach's Financial Facts." A description of the same property by a Nova Scotian mining engineer says "in my opinion it would require a very large outlay to put this mine

in condition for a daily output of 300 tons, and such a development would not be warranted by the present holdings." This same mine produced in 1908 the large output of 2,726 tons, of which amount the former owners raised 1,287 tons.

Comparisons are odious, but we feel bound to remark that a great deal of the information which is disseminated in the United States with reference to Canada is, shall we say, "roachy" in character.

#### QUEBEC.

Mr. J. E. Hardman, S.B., of Montreal, was in Thetford recently, looking over some Asbestos ground for a client.

The Montreal fiscal agents of the Compton Gold Dredging Co., having failed to make good on their agreement to provide funds for a dredge, by May 1, Kennedy & House, of Beebe, are now calling for the return of their property, as other parties are ready to take it up and put on a dredge this season.

It is reported that the Eustis people are about to re-open the nickel property at Brampton Lake.

The asbestos Merger, and the sale of a few properties has had the usual effect, namely, farmers having a show of serpentine, or hornblende, expect to get anywhere from \$25,000 to \$100,000 for a few acres, while one with any real asbestos goes up out of sight. And there will be the usual result. It is one of the unfortunate things about mining—people will lose their heads, eventually be disappointed and blame anything and everything for their own folly. We have yet to see what the ultimate result of the merger with its \$25,000,000 capitalization will be.

Meanwhile, prices are on the aeroplane. The writer had an option on 100 acres last season for \$1,500, and allowed it to expire. Now the owner has leased it for \$10,000 and gets \$100 per month during life of the option. Truly, there's a time to catch bears.

The Eastern Canada Smelter Co., which has an option on Mr. J. McDonald's copper property in Weedon, is sinking a new shaft. Some handsome ore from the property can be seen in the Company's office, Sun Life Building.

A meeting of the Directors of the Eastern Canada Mines Company was held recently and properties offered the Company discussed, and several declined. Plans were made for taking over of some promising claims, and the business of the Company put on a satisfactory basis.

The Company has a deal in prospect on one of its holdings, Le Chat Noir, a large placer.

Mr. Geo. Lewis, M.E., and Mr. C. A. Parsons arrived in Sherbrooke, June 15, and with Mr. Kenneth E. Kennedy drove to the property near Little Lake, recently purchased from Mr. Parsons by New York people. Mr. Lewis is here for the purpose of advising on the best means of working the placer ground, and also of examining the quartz veins on the property.

#### ONTARIO.

Cobalt.—On June 4 a general meeting of the shareholders of the Temiscaming & Hudson Bay Mine was held to discuss a place for the recapitalization of the company. It is proposed to form a new company having a capital of from \$3,500,000 to \$5,000,000, the shares being of a par value of \$1.00. The issued stock of the present company is only 7,761 shares of a par value of \$1.00 each, but the true value of each share is so great that the stockholders have a commodity that, while of

great value is not easily disposed of to advantage. There seems to be a general feeling in favor of some scheme of recapitalization whereby the shareholders will have certificates that may easily be bought or sold on the exchange. Although no definite arrangement was decided upon at the general meeting it would not be surprising if some action were taken in the near future. Up to date this company has returned to the shareholders, dividends to the extent of 13,300 per cent. on the issued capital.

At the Ophir Mine the foundation for the compressor is finished and the compressor will probably be in place by about June 8. The boilers are being bricked in and the management expect to have the plant in running order about June 21.

The shaft of the Hargraves has reached a depth of 275 feet, and at this level a cross-cut will be driven. Some work has also been done at the 75 and 175 foot level, but up to date good silver values have not been encountered.

The directors of the Trinity Mining Company have decided to go into liquidation. This company owns two claims in Coleman Township.

The values have given out in the new vein at the Beaver, at a point where a change in direction of the vein occurred. This, however, is a common thing with the veins in this locality and the management expect to get the values again in a short distance. The diamond drills working in the mine have struck two new calcite veins which have not been found as yet to carry silver values.

There have been two accidents within a week, caused by drilling into missed holes, whereby four men were very seriously injured. It is too much to say that a more rigid mine inspection would have prevented these accidents, but it is undoubtedly true that it would prevent some of the fatalities occurring. The inspection given the Cobalt camp is excellent, so far as it goes, but the inspector has altogether too much work to do, to give this district the attention it deserves. A permanent inspector for the camp is badly needed, and the Government is greatly to be censured that one has not been appointed before this. Neglect of this matter has already caused the loss of too many lives.

The Nipissing Central Railroad Company has completed their surveys for the electric line to be run between Cobalt and Haileybury, and the contract for building has been let to the Nova Scotia Construction Company, of Sydney, C.B. Work will be started at once and it is estimated that the cost will be about \$125,000. Power will probably be obtained from one of the companies bringing power into the town.

The cyanide plant of Buffalo Mine, to be operated in connection with the present mill, is about completed and will probably be started about the 1st of July. For the fiscal year ending May 10th the average assay of the mill rock was 43 ounces and a total saving of 86.4 per cent. was made. The average value of the concentrates was 1,500 ounces. Commencing with July a complete monthly statement will be issued to the stockholders giving the details of the mining operations and cost and profit of the ore milled and mined.

A new company known as the Lang Caswell Cobalt Mines Company, Limited, has been formed to take over the holdings of the Lang Caswell Syndicate, which consist of 440 acres in the first concession of Lorraine. The capital of the new company is \$1,500,000, all of which was subscribed for by the directors at a meeting held a short time ago. A shaft, sunk to a depth of over 60 feet is being continued to the 100-foot level. Another shaft will be sunk to the same depth on the best showing on No. 1 property, and these two workings will be connected by a cross cut.

The Pontiac Mine has shut down for the time being owing to the fact that the workings have progressed beyond the point

where steam can be successfully used for the drills. It is understood that negotiations are under way for the purchase of air from the King Edward or the Silver Cross Mines, and if such are satisfactorily completed, work may be resumed. In the meantime surface prospecting is being carried on.

Mr. M. McCallum has resigned his position as superintendent of the Pan Silver and he will be succeeded in that capacity by Mr. J. A. Skeene. The No. 4 shaft has reached a depth of 215 feet and at this point a station is being cut. A cross cut will be run to tap No. 4 vein.

The Silver Cliff Mine has a force of 30 men at work doing development on No. 1 and 2 veins. These workings will probably be connected about the last of June. Work of any great extent will not be undertaken until the hydraulic air is ready.

A strike has been made on the No. 7 vein of the King Edward in the raise, 45 feet above the 150 foot level where the vein widened from a mere stringer to between 2 to 4 inches of high grade ore. No. 7 vein runs parallel to No. 5, on which a new ore body was discovered a short time ago. A prospecting tunnel is being driven into the hill from the side of Cross Lake, but nothing of value has as yet been discovered. The mill is putting through about 20 tons of ore a day.

The Townsite Mine is to open up again about the 1st of July. The necessary capital was raised by the issue of debentures to the amount of \$100,000, which were largely subscribed for in England.

The Nancy Helen Mine is getting ready to commence their diamond drilling operations from the 190-foot level of the main shaft. Other underground operations have been suspended in the meantime.

The main shaft of the Wettlaufer Mine in South Lorraine has been sunk 70 feet, and in the first 60 feet \$15,000 worth of ore was taken out.

The capacity of the mill at the Reddick Mine at Larder Lake will be increased by the addition of a tube mill. Twenty men are employed in sinking the shaft, trenching and cutting timber. At the Cleopatra Mine, a large force of men will be employed this summer in prospecting the surface. It is believed that Mr. George Taunt, who is a prominent stockholder in the Chesterfield and the Lucky Boys, is trying to arrange for a lease of the mill on the Harris Maxwell for the purpose of making a mill run of the ore from the former properties.

There is considerable disappointment around Gowganda, as there is not the number of people going into the country that was expected. On the whole the Miller, Everett and Shanty Lake sections seem to be the best and there is a good deal of work being done on the properties there. The Everett Silver Cobalt Syndicate have erected two permanent camps at Everett Lake and are employing 100 men. This company has twenty-one claims that were purchased from the Miller Lake & Everett Mines Co., Limited. A find of silver has been made on Cartwright's Claim, adjoining the Blackburn Mine on Everett Lake. The vein was traced from the latter property. The Blackburn is one of the most promising mines in the new district, and now has a complete plant running. On McRae's property at Shanty Lake there is silver showing in eleven veins, and considerable development work has been done. The German Development Company has a force of men working on their properties at Shanty Lake. On the Burns property, in the same section, a new two-inch vein of high-grade ore has been encountered. On June the 5th there was a rush to Smoothwater Lake where silver was reported to have been found. There is only a small diabase area, however, and there is a good deal of staking on the quartzite. The Welcome Lake section is receiving considerable attention at the present time and several promising discoveries are reported to have been

made. There was also a small rush to Duncan's Lake but most of the prospectors returned not greatly enthused over the prospects. A small rush has taken place to Rapid Lake, which is to the north of Temagami. The Government is strictly enforcing the law that permission must be obtained before doing any work and the filing of work will not be recorded unless such permission has been granted. So far the stakers around Shining Tree Lake have been refused permission to work on account of the value of the pine. There are now two passenger canoe companies operating between Stoney Creek portage and Gowganda, carrying passengers in one day. The rates are \$9.00 for the return trip. Stoney Creek portage is thirteen miles above Elk Lake and is reached by gasoline launches. One of these companies, known as the United Mining & Transportation Co., also handles freight, and they now have eighteen large freight canoes in service. The rate for supplies is \$7.50 per 100 pounds. This same company has two teams of horses for handling freight on the portage into the east branch of the Montreal River. The new line of boats, known as J. R. Booth's line, operating between Latchford and Elk Lake in competition with the Upper Ontario Navigation Company, has rendered the service much better for passengers. The Government is building a wagon road between Elk Lake and Gowganda, and the preliminary surveys have been completed. It is estimated that the distance will be cut down about seven miles and also that the muskegs and heavy grades will be avoided. It will not be long before mail will be brought into Gowganda by pack horses. At present only first-class mail is carried. The first newspapers for three months arrived in camp on June 10th. Mr. A. A. Cole, engineer for the railway commission, made a trip into the district to look into the resources to see if they warranted railway construction.

The town of Elk Lake has had a very rapid growth since last fall and it can supply more first-class hotel accommodation than Cobalt. Surveys have been made of Mountain Chutes to estimate the available power to supply the Elk Lake mines. Silver Lake, six miles to the west of Elk Lake, there are four five plants installed and running. The Big 6 at Miller Lake is now working part of its plant and it is expected that the rest will soon be running.

The directors of the Temiskaming Mine, at their meeting held a short time ago, decided not to declare the regular quarterly dividend of 6 per cent. They state that the Company intends to erect a concentrator with a capacity of from 75 to 100 tons a day. They also wish to build up a large cash and ore reserve. It is understood that the mine is rather short of ore.

New York parties have taken over the Monarch Claim, lying to the west of Sosagmaga Lake, and a force of men has been started doing surface prospecting. The claim consists of twenty acres.

The Silver Cliff Mine has been sold to Pittsburg capitalists. Captain Jeffrys, formerly of the Chambers-Ferland, will take charge of the operations.

During the coming summer the Coniagas will double the output of their present mill. Thirty stamps will be added and so the necessary tables. No addition will be necessary to the crushing and jigging end as the capacity is already 300 tons a day. The smelter at Thorold, which started to take custom ores a short time ago, is working up to its full capacity.

#### BRITISH COLUMBIA.

**The Boundary.**—It was in 1898 that the shade known as Dominion Copper interests took the first degree; later on the Montreal & Boston Consolidated took the floor, and put the concern through the second; in the fall of 1905 Salt Lake and

New York capitalists undertook to put on the good old third, and between the whole team the Dominion Copper certainly had quite a time of it. When old Dominion came in blindfolded for the third he had a prosperous sort of look, but a few whirls of the goat—or lamb—and he lost his coat of anticipated dividends; then off came the bright waistcoat of expected profits, and he tumbled into a ragged old coat of loss and increasing debt and was soon sliding down an incline to goodness knows where. The big bump occurred in Vancouver, B.C., on June 4th, when the property of the Dominion Company was bought by the Chas. Hayden interests of New York for \$261,500. This amount will not go far toward paying the \$800,000 outstanding bond issue and the interest thereon, to say nothing of the other debts of the company which will likely go begging, with the exception of the amount due the miners for wages, which the buyers of the property "consider" should be paid prior to anything else. It seems strange that the Protective Committee, if they had the backing they claimed, did not put in an appearance at the Vancouver sale, the property being bid in at only \$1,000 over the reserve price; the Hayden interests, represented by M. Weinman, being the only bidder. And then a short while ago it was said that one or two of the big Boundary consolidations had offered \$350,000 or over for the Dominion mines. They must have been observing some unwritten rule of mining etiquette when they did not get in and bid, and yet it may be that these big concerns have their hands full and do not wish to undertake the development work that ought to be done in these mines. It is taken for granted that a new company will be organized along the lines already set forth by the Reorganization Committee, to take over the property recently acquired, which comprises the Rawhide, Brooklyn, Stewwinder and Idaho claims, the Boundary Falls smelter, mining machinery, supplies, etc.

The Granby shipments are running about 20,000 tons per week. At the Grand Forks smelter four of the enlarged furnaces are now in operation, numbers three and four having been blown in a week or ten days ago. The altered furnaces are giving very good satisfaction, and the work of augmenting numbers five and six has been started. It is hoped that the whole battery of eight furnaces will have been gone over by October. Many small additions are made to the Granby plant each month working toward higher efficiency. An 8x12 triplex pump was placed on the 400-foot level of the mine last week, where it will serve the dual purpose of taking the water from the mine and forcing it to a supply tank 500 feet up the hill.

For the week ending June 12th the Snowshoe mine shipped 2,950 tons of ore, this being the largest week's shipments from this property this year. The Sally mine also appears on the shipping list with 23 tons to Trail smelter, making a total of 39 tons for this high-grade property since May 22nd.

It should certainly be gratifying to the mining interests of this Province to note the amount of work the Geological Survey of Canada is planning to do here this year. This work will be carried out on a broader scale than ever before, and in most instances the parties are already in the field. The Tulameen section of the Similkameen district, Phoenix, the Sloean, Sheep Creek, West Fork of Kettle River, Texada Island, Vancouver Island and the Hazelton section of Skeena River are to be given attention and data compiled that will be of inestimable value to future mining operations in the districts named.

It is stated that the capitalists for whom M. K. Rodgers has bonded the Nickel Plate group intend to operate the property on an up-to-date scale when arrangements are finally made. The property has been thoroughly sampled, and those interested have all the available data at hand to help them in planning for intelligent future work. The group consists of the Nickel Plate, Sunnyside and Woodland Fr. claims, and the 40-stamp mill is situated at the foot of the hill near Hedley. Some glory-

hole work has been done on the large lodes, this ore generally averaging \$14 per ton; some of the veins assay \$80 per ton, while frequently very rich pockets have been opened up.

**Rossland.**—The Le Roi 2, Ltd., has let a contract for the deepening of its main (Josie) shaft from the 900 to the 1,200 level. This work has not been undertaken without due study of conditions and much diamond drill exploration in the ground to be opened up. Rich ore bodies have been located below the 900-foot level in Le Roi 2 ground, and it is expected that similar ore will be opened up from the 1,200 level to that found in Le Roi ground at about this level. The work of sinking this 300 feet of shaft will cost over \$18,000.

Rumour is persistent that the Le Roi will resume work in the near future, but while it is understood Mr. McMillan is making good headway in London, it is not likely that work will be started on the proposed development for another month or two. A local syndicate has expressed its willingness to take over and work the Le Roi on a lease, but it is not likely that the Le Roi Company could afford to lease its mine at this time.

A rich-looking vein from two to three feet wide has been located on the War Eagle claim of the Consolidated group. It is probable that this vein upon development will prove as rich as the Peyton vein of the Le Roi and other very rich surface lodes that have been uncovered on that property, the claims of the Le Roi 2, Ltd., etc. Last week at the Consolidated smelter at Trail another large furnace was blown in, giving this plant four big copper furnaces in addition to its lead stacks. The expansive spirit of the Consolidated again made itself evident during the past week, when the Alice mine at Creston was secured by this concern. The Alice is a silver-lead mine of promise, and will prove a valuable acquisition to the mining and smelting operations of the Consolidated.

As we suggested at the end of last year, there has been a small increase in the metallic production of this province, while

the coal mines about held their ground. A preliminary report on the mineral production of Canada shows that the increase for the Dominion amounted to nearly half a million of dollars. Silver showed an increase of 72 per cent., for part of which increase the lead bounty may account, although it is shown that lead showed a slight falling off. The total output was a little over \$87,000,000. Gold showed an increase, most of this being taken from the lode mines of the Rossland-Trail Creek district. The copper increase was 14 per cent. the Boundary mines taking out seven millions pounds more than during the previous year. The lead, amounting to \$1,920,487, was all mined in British Columbia. The coal production is shown as 2,329,600 tons, value \$7,280,000, against 2,364,898 tons mined in 1907.

**Vancouver.**—There are several big syndicates that will do extensive development work on the rich copper deposits of Moresby Island this summer. The outlook for this district seems bright. The deposits are large, rich in copper, gold, and silver, and will flux very readily. The Japanese owners of the Ikeda group on Ikeda Bay were in a manner pioneers in this rich district. There are now 65 men working at this property nearly all Japanese. About 1,000 tons per day is being shipped to the Tyee smelter, Ladysmith, V.I., the freight rate being \$1.50 per ton. Average ore found at depth in the hill assays 7 per cent. copper and \$3.50 per ton in gold. The hand sorted ore carries 12 per cent. copper, \$5 gold, and as high as 60 oz silver per ton. The Granby people have interested themselves in a group of copper properties on the west coast of Moresby Island, as have also a couple of big American mining syndicates and if the values are found at depth as good, or anywhere near as high, as are now found on the surface, the Moresby Island district will be an important factor in the copper market in the not distant future.

## GENERAL MINING NEWS.

**Sydney, N.S.**—The Steel Company is making a new record at the blast furnaces and open hearths. For several days past three blast furnaces turned out over 900 tons a day. The open hearths produced nearly 14,000 tons the first half of the month. One furnace produced recently in one day of 24 hours 450 tons. All departments of the plant are running at high pressure and June is expected to be a big month.

### QUEBEC.

**Sherbrooke.**—A. W. G. Wilson, of the Mines Branch, Ottawa, is making Sherbrooke his summer headquarters. He is to report upon the mining properties and activities of the Eastern Townships.

The Ascot Copper Mine, south of Acton, was purchased some time ago from the Hon. Henry Aylmer. The property comprises 275 acres. It is being equipped with machinery. Mr. John McCaw, of Sherbrooke, is in charge. Very rich, self-fluxing copper ore is being worked.

### ONTARIO.

**Cobalt.**—Fifteen parcels of the Gillies limit were disposed of by tender for a total of \$74,000.

**Port Arthur.**—The Atikokan furnace is soon to be blown in. A new coke drawing machine has been installed by General Manager J. Dix Fraser.

**Madoc.**—There is promise of greatly renewed mining activity in and around Madoc and in outlying districts.

### SASKATCHEWAN.

Near Paynton a discovery of gold and silver was made early in June. A rush ensued at once. No particulars are yet to hand.

### ALBERTA.

**Strathcona.**—On Friday evening, June 11, two miners were severely burned by an explosion of gas in the Twin City coal mine.

### BRITISH COLUMBIA.

**Phoenix.**—The only bidder for the Dominion Copper properties at Phoenix was Charles Hayden, of New York. The sale took place at Vancouver on the morning of June 4th. Mr. Hayden's bid was \$261,500. This was accepted. The pro-

perties near Phoenix include the Brooklyn, Idaho, Stenwinder, Rawhide, and Mountain Rose mines. Mr. Hayden will operate these properties. In response to an enquiry concerning the unpaid wages of Dominion Copper workmen, Mr. Hayden telegraphed his assurance that these, as the most sacred of all debts, should certainly be paid in cash in full.

**Moyie.**—The tailings from the St. Eugene concentration at Moyie are being utilized by the C.P.R. for ballast.

**Rossland.**—A contract has been let for sinking the main shaft of the Le Roi No. 2 from the 900 foot to the 1,200 foot level. The dimensions of the tunnel will be 7 x 16. Sinking will progress at the rate of about 75 feet per month.

**Phoenix.**—The Granby Consolidated Company has presented three lots to the town of Phoenix, as a site for a large public

school. The building at present used is too small and is inconveniently near one of the company's ore crushers.

A company has been formed to develop the Buster mineral claim on the West Fork.

**Vancouver.**—On June 7 a shipment of bar silver from the Consolidated Smelter, Trail, B.C., passed through this port, en route to China. The value of the shipment is estimated at about \$30,000.

**Nelson.**—News has been received of the death of Mr. R. J. McPhee at Spokane, on June 13. Mr. McPhee was a native of Prince Edward Island. He was formerly an active figure in mining in Nelson and the Slocan.

## MINING NEWS OF THE WORLD.

### GREAT BRITAIN.

On May 28 the South Wales coal-owners distributed to all their workmen a notice terminating their contract of service on June 30th. This affects 150,000 men.

Scotch steelmakers in private conference have agreed to reduce ship plates and angles 10 shillings per ton for prompt delivery.

The position of the Scotch coal trade is most acute. Owners are arranging to enforce a reduction in wages of 12 1-2 per cent. The miners are holding out for a minimum rate of 6 shillings per day. Eighty thousand miners are involved in this dispute.

### AUSTRIA.

The Galician oil producers have entered into a contract with the Standard Oil Company, by which the latter have undertaken to build a number of reservoirs for raw oil. The Galician oilmen will pay a rent of £75,000 for four years, after which half the reservoirs will become their property and half will remain with the Standard Oil Company. The contract is very favorable to the Standard Oil Company, as the rent must be paid whether the tanks are full or empty.

### SOUTH AFRICA.

Thirty-five Rand companies report an increase of profits for May of £37,104.

Great activity continues on the Randfontein Estate. Large orders of machinery have been delivered. The western Rand Estate is to be operated on a large scale.

### MADAGASCAR.

The Madagascar Oil Development Company, a new Anglo-French petroleum undertaking, has been formed for the purpose of

exploiting the recently discovered oil-region on the west coast of Madagascar. The products will be imported free into France as Madagascar is a French Colony. Foreign producers have to pay a duty of 90 francs per ton on crude petroleum, and 120 francs per ton on refined.

### NEW ZEALAND.

The output of gold from New Zealand mines during May amounted to 46,525 ounces, valued at £185,271, as against 45,017 ounces, valued at £179,487, during the corresponding month last year. The output of silver was 175,958 ounces, valued at £17,492, as against 164,635 ounces, valued at £16,670 during May, 1908.

### UNITED STATES.

Cripple Creek district produced \$1,360,838 in gold during May. This yield came from 57,835 tons of ore, an average per ton of \$23.74. Apparently these returns are incomplete as no reports were received from Stratton's Independence mill.

Mining costs are being reduced to very favourable figures at Goldfield, Nevada. One company reports the following costs: Stopping, \$2.82 per ton; development, \$1.10 per ton; transportation 13.3c. per ton; milling \$2.44 per ton, total \$6.49 per ton.

The total production of gold in the Tonopah district, Nevada, for the week ending May 28, estimated to be about \$140,000.

A copper smelter, to cost one million dollars, is to be erected at Parker, Yuma County, Arizona.

The largest gold dredge yet constructed is being equipped at Mangold, Yuba County, California. It will cost, when completed, about \$200,000.

The Standard Oil Company has commenced oil-drilling operations at Oakland, Douglas County, Oregon. Leases have been secured on 30,000 acres of land.

The copper mines of Utah exceeded all previous records during the months of April and May. In each month the output of copper went over 10,000,000 pounds.

## COMPANY NOTES.

The International Nickel Co. has declared an initial dividend of 1 per cent. on the common stock, payable September 1. It is believed in well-informed quarters that the rate will be paid quarterly.

The Crown Reserve directors have declared the regular quarterly dividend of six per cent. and bonus of nine per cent. on the stock, payable July 15, to shareholders of record June 30. Books close from July 1 to July 15, inclusive.

During May the Nipissing Company mined ore of an estimated net value of \$151,930 and shipped ore of an estimated net value of \$168,224. This compares with a production of estimated net value of \$149,739 in April and estimated net shipments of \$96,492 in that month.

The Nipissing Mines Co. has declared the regular quarterly dividend of 3 per cent. and an extra dividend of 2 per cent., payable July 20th. Books close on June 30th and reopen July 15th. The statement submitted at the meeting showed a surplus as of June 14th of \$1,092,000, consisting of cash on hand, ore at the smelter, in transit and at the mines.

Following is the report of Manager Paul E. S. Couldrey on the Le Roi 2 for the month of April, which was issued from the London office of the company on May 25th:

The output for April was approximately 2,610 tons. Development work has been done as follows:—

**400 Foot Level.**—The 400 cross-cut was advanced a distance of 68.5 feet, and ore was drifted on for a distance of 54.5 feet. Total distance, 123 feet. The average assay met with was 1.21 oz. gold and 3.2 per cent. copper, over a width of 12 inches. Twelve samples were taken. The ore will probably be found to extend farther either into the foot or hanging wall than the above 12 inches would seem to indicate.

**900 Foot Level—Cutting Pocket.**—A drift of 45.5 feet was put in here to connect with place where bottom of pocket will be.

**East H. Intermediate Drift.**—This was advanced a distance of 71 feet and broke through into East H., No. stope. The average assay met with here and in the stope was .53 oz. gold and 3.8 per cent. copper, over a width of 1 foot 9 inches. Twenty samples were taken.

**301 Stope.**—This stope has broken through to tramway tunnel during the month. The average of samples taken was 1.12 oz. gold and 2.3 per cent. copper, over a width of 2 feet 3 inches. Thirty-four samples were taken.

**42 Stope.**—This stope is still very spotty, especially at the east end. As we get further up, however, we shall confine our attentions more to the good ore at the west end. Eighteen samples were taken, the average assay of which was .27 oz. gold and 1.1 per cent. copper, but the ore is too scattered to give any definite width.

**423 Stope.**—This stope, which has only been attacked in the level itself, and not taken out in the back up to the present, shows an average of 2.06 ozs. gold and 5.0 per cent. copper. Nineteen samples were taken and the average width over which they were taken was 3 feet 3 inches. There are several streaks lying side by side, however, and the total width of ground taken

out is very wide, being 22 feet at the east end with ore still showing in the footwall. The average assay taken across the whole width, including waste and everything, would of course be lower than the above, but the ore from here is quite easy to sort, and the grade of ore picked out after sorting should not be less than the above. This ore also exists on the 500, but there it is much shorter in length being cut off by two converging dykes.

**428 Stope.**—This is really a large raise which has been started so that a chute can be put in and work started at a later date for the ore met with in Diamond Drill Hole No. 160. One stringer about 6 inches wide assayed 1.14 oz. gold and 3.8 per cent. copper, but it pinched out almost immediately.

**Stope 32 (500).**—The waste pillar of ground met with in this stope is now giving way to good ore again. The average assay from the back of this stope was .96 oz. gold and 5.4 per cent. copper, over a width of 21 inches. Forty-two samples were taken.

**East H. No. 1 (500).**—There is a little more ore to be taken out of here yet and it may in one place go through to the 300 level. The average assay met with was .53 oz. gold and 3.8 per cent. copper over a width of 21 inches. Twenty samples were taken.

**702 Stope (700).**—No fresh ground was broken here, but stulls are being put in, and we hope to start breaking ore very soon.

**Shaft Timbering.**—This was completely finished on April 21, and the unloading pocket was started the same day. We shall push the work as rapidly as possible, and start sinking immediately afterwards. Two drills will be put in pocket raise as soon as there is room for them.

At a meeting of the directors of the Temiskaming Mining Company on June 12, at Haileybury, it was decided to pass the dividend for the current quarter. The directors at the meeting arranged for the erection of a concentrator on the company's property without delay.

The following official statement to the shareholders was issued afterwards, signed by B. E. Cartwright, R. T. Shillington, J. L. Wheeler, R. H. Cartwright, and Alex. Fasken:—

"In view of the fact that your directors have decided not to pay a dividend for the current quarter, they think it well to explain to the shareholders the present condition of the mine and outline the future policy.

"Your directors believe it to be in the best interests of the shareholders to build up a large cash reserve and ore reserve and take advantage of the low-grade ore already produced and being produced daily in development work and production of the high-grade ore.

"Our production of high-grade ore is being maintained, the ore bodies proving as rich as ever at the 250-foot level and by means of a winze to a depth of 300 feet.

"Up to date no revenue has been obtained from the low-grade ores, and at a conservative valuation the ores in the dumps ready for concentration, will net the company \$500,000, and in addition to this there are being produced an average of 100 tons per day of concentrating ores of an average net value of \$15 per ton.

"Your directors think that advantage should now be taken of the low-grade ores, and are proceeding to install a concentrating plant with a capacity of from 75 to 100 tons per day, at an estimated cost of from \$75,000 to \$100,000, and expect that the plant will be in full operation before the end of this year.

"The installation of the plant should add at least \$400,000 yearly to our net revenue, and there is sufficient ore in sight to maintain the output of the plant for many years to come.

"Your directors have the fullest confidence in the future earnings of the company, and invite all shareholders to make a personal inspection of the mine."

The following is the proposed plan under which the reorganization committee of the Dominion Copper company are now working. The committee, which purchased the property at the foreclosure sale, will transfer it to the New Dominion Copper company which will issue the following securities: \$500,000 of 6 per cent. 10 year income bonds, convertible into stock at par, \$5 per share; 250,000 shares of common stock of a par value of \$5 per share. Present bondholders will take new stock for their bonds on the basis of 210 shares of new stock for each \$1000 bond. This will absorb 168,000 shares of the new stock. Creditors will receive 20,000 shares of new stock in the proportion of 20 shares for each \$100. Present stockholders upon turning in their present stock and subscribing at par for the new bonds on the basis of one hundred dollars of bonds for each \$100 of present shares will receive in addition to the bonds subscribed for 10 shares of new stock for each 100 shares of present stock, this calling for 50,000 shares. Underwriters will receive 12,000 shares of the new stock which will account for the entire 250,000 shares.

The Dominion Coal Company has declared the regular quarterly dividend of one per cent in the common stock, payable July 2,

to stockholders of record June 18. Books close June 18 to July 2, inclusive.

At the Annual Meeting of the Chambers—Ferland Mining Co. The important items in the statement of assets were: Cash in bank, \$54,799; ore in transit, and at smelter, \$21,544; ore on hand \$15,257.

The statement showed a balance, including these items, of roughly, \$82,000. The property was stated to be in satisfactory shape, and nothing was said as to the prospect of a dividend. The Chambers-Ferland being in a condition of development, the payment of a dividend is still in the prospective.

The other business of the meeting was the re-election of the old board, as follows: W. C. Chambers, president; Harper Armstrong, vice-president; Alexander Fasken, secretary-treasurer; Arthur Ferland, W. B. Russell, George H. Sedgwick, and A. P. Struthers.

#### LA ROSE CONSOLIDATED MINES COMPANY.

A dividend at the rate of 3 per cent. for the quarter ending 31st May, 1909, and a bonus of 1 per cent. has been declared upon the outstanding capital stock of the company, and will be paid 20th July next to shareholders of record at the close of business on 1st July, 1909. By order of the Directors, the transfer books will be closed from the close of business on 1st July, 1909, and remain closed until 10 a.m. on 21st July, 1909.

Dated the 17th day of June, 1909.

LA ROSE CONSOLIDATED MINES COMPANY,

D. A. Dunlap, Secretary-Treasurer.

## STATISTICS AND RETURNS.

The Kerr Lake Mining Co. reports its output for May at 220,000 ounces of silver. The main drift on No 7 vein at the 150-foot level was driven 72 feet on a continuous pay streak, and the ore showing for this 72 feet is stated to be as good as any in the history of the mine. The pay averages ten inches in width, and is of the average high-grade ore. A new vein showing high silver values was discovered by trenching on the east side of the property.

#### COBALT ORE STATEMENT.

For the Week Ending June 12th, 1909.

| Other mines ..... |       | 7,153   |
| Total .....       | 7,715 | 155,941 |

The total smelter receipts for the past week were 27,685 tons and for the year to date 733,030.

L. Vogelstein & Co., New York, report the following figures of German consumption of foreign copper during the months January-April, 1909:—

|                            |              |
|----------------------------|--------------|
| Imports of copper.....     | 49,323 tons. |
| Exports of copper.....     | 2,703 tons.  |
| Consumption of copper..... | 46,620 tons. |

As compared with consumption during the same period in 1908 of 53,810 tons. Of the above quantity 45,026 tons were imported from the United States.

#### TORONTO MARKETS.

**Metals—June 22**—(Quotations from Canada Metal Co., Toronto.—These prices are slightly higher than wholesale prices obtainable on large orders.)

|                                    |
|------------------------------------|
| Spelter, 5½ to 5¾ cents per pound. |
| Lead, 3½ cents per lb.             |
| Antimony, 8½ cents per lb.         |
| Tin, 31 cents per lb.              |

#### Copper—

|                                 |
|---------------------------------|
| Casting, 13¾ cents per lb.      |
| Electrolytic, 13¾ cents per lb. |
| Lake, 14 cents per lb.          |

**Ingot Brass**, 10 to 14 cents per lb.

#### Coal—

|                                                 |
|-------------------------------------------------|
| Anthracite, \$5.50 to \$6.75.                   |
| Bituminous, \$3.50 to \$4.50 for 1¼ inch. lump. |

**Pig Iron—June 22**—(Quotations from Drummond, McCall & Co.)

|                                                      |
|------------------------------------------------------|
| Summerlee, No. 1, \$21.75 (f.o.b. Toronto).          |
| Summerlee, No. 2, \$21.25 (f.o.b. Toronto).          |
| Midland, No. 1, \$17.75 to \$18.00 (f.o.b. Midland). |

#### MARKET REPORTS.

##### Coke.

**June 18.**—Connellsville Coke, f.o.b. ovens:—

|                                                 |
|-------------------------------------------------|
| Furnace coke, prompt, \$1.50 to \$1.60 per ton. |
| Foundry coke, prompt, \$1.80 to \$1.90 per ton. |

##### Metals.

**June 18.**—Tin, straits, 29.50 cents.

|                                                   |
|---------------------------------------------------|
| Copper, prime lake, 13.50 cents.                  |
| Electrolytic copper, 13.125 cents.                |
| Copper wire, 15 cents.                            |
| Lead, 4.35 to 4.40 cents.                         |
| Spelter, 5.45 cents.                              |
| Sheet zinc, 7.50 cents.                           |
| Antimony, Cookson's, 8.25 cents.                  |
| Aluminium, 21 to 24 cents.                        |
| Nickel, 40 to 47 cents.                           |
| Platinum, \$22.50 to \$23.50 per oz.              |
| Bismuth, \$1.75 per lb.                           |
| Quicksilver, \$44.50 to \$45.00 per 75-lb. flask. |

#### MARKET NOTES.

**Silver.**—During the first week of June, India was a buyer of cash silver, but a seller of forward. Business was large. The Punjab crop forecasts are distinctly favorable. Wheat will, it is estimated, exceed the average output by 22 1-2 per cent. Other crops show up even better. Thus prospects are good for a strong silver market throughout the year.

The Commission appointed by Governor Hughes to investigate the methods of various exchanges, reported thus upon the Metal Exchange:—"Similar, but equally deceptive, is the method of making quotations on the Metal Exchange. In spite of the apparent activity of dealings in this organization in published market reports, there are no actual sales on the floor of the Metal Exchange, and we are assured that there have been none for several years. Prices are, however, manipulated up and down by a quotation committee of three, chosen annually, who represent the great metal selling agencies as their interest may appear, affording facilities for fixing prices on large contracts, mainly for the profit of a small clique, embracing, however, some of the largest interests in the metal trade.

"These practises result in deceiving buyers and sellers. The making and publishing of quotations for commodities or securities by groups of men calling themselves an exchange, or by any other similar title, whether incorporated or not, should be prohibited by law, where such quotations do not fairly and truthfully represent any bona fide transactions on such exchanges. Under present con-

ditions, we are of the opinion that the mercantile and metal exchanges do actual harm to producers and consumers, and that their charters should be repealed."

Remarkable pegging activity is reported from the West Rand. 8000 claims have been pegged since September.

Up to June 1 three drills had withdrawn from the public competition now in progress.

The Rooiberg tin mines started milling on May 31.

Of the 7,734 Chinese in the Transvaal on April 30, seven died during May and ten were removed, leaving 7,717 in the country on May 31st.

The Transvaal Government has appointed a Commission to inquire into and report upon the question as to whether any portion of the moneys accruing to the Crown from the leasing and disposal of rights of mining in Crown lands, etc., should be paid to any class of persons, and if so, to what class or classes, and in what proportion.

### COMPANY NOTES

Directors of La Rose Consolidated Mines declare the quarterly dividend of three per cent., along with a bonus of one per cent.

Total production, June 1st, 1908, to May 31st, 1909, one year:

| Shipments.                                        | Tons.    | Ounces<br>Silver. | Net Value<br>at Mine. |

A number of cities and towns in the United States may obtain their light, heat and power direct from peat bogs in the near future. The statement is made by Federal experts that millions of dollars worth of fuel lies undeveloped in the swamps and bogs of the country, awaiting only the genius and business ability of the American before it drives the wheels of progress. Its value, on a basis of \$3.00 a ton, roughly guessed at by experts of the Geological Survey, who have been studying the peat deposits for some time, is more than thirty-eight billion dollars—more money than is represented in all the property, stock, implements and buildings owned by the farmers of the United States.

With the coal supply being used at a tremendous rate, peat is expected to become a most important auxiliary fuel and one that will prolong the life of the coal itself. An important fact which leads the experts to believe that peat will soon come into

quite general use in certain parts of the country is that it is as a rule found in quantities in regions far removed from the coal fields, so far that the cost of transporting the coal amount to several times the cost of the fuel itself at the mines.

The states containing the greatest amount of peat are the eastern Dakotas, Minnesota, Wisconsin, Michigan, Northern Iowa, Illinois, Indiana, Ohio, New York, the New England States, New Jersey, portions of Virginia, North and South Carolina, Georgia and Florida.

A thorough investigation of the peat resources is now being undertaken by the Geological Survey, not only as to the amount of peat and its location, but also its use. Prof. Charles A. Davis, of the Technologic Branch, has general charge of the investigations, while Prof. Robert H. Fernald, consulting engineer in charge of gas producer tests, is endeavoring to find the value of peat as a fuel for heating and power purposes. The latter but recently returned from a trip to Europe where he investigated the uses of peat and found the older countries much farther advanced along this line than the United States. Professor Fernald returns with the belief that peat will soon be extensively used in the United States. In Ireland, he found that peat was being used generally for domestic purposes but not by the manufacturing establishments. "Sweden is dotted with peat deposits and its bogs are now being extensively utilized for power purposes," says Prof. Fernald. "During the last eight years new bogs have been constantly added to the list until bogs producing from 2,000 to 5,000 tons of dry peat for power purposes per year are found on every hand. The consulting engineers who have installed some of these plants are unquestionably working in the right direction, placing the power plant directly in the peat bog and transmitting the electric current to the surrounding towns. The current is being used for manufacturing purposes and also for lighting both the streets and houses. The installation of the power plant in the bog or at the mine has been advocated in this country by the Technologic Branch of the Survey for installation of several thousand horsepower only, yet this principle is applied in Sweden to small plants and may be feasible in certain parts of this country."

"Another development in the line of peat industry which promises splendid returns is the use of peat in by-product recovery gas plants. From these plants both gas for power and sulphate of ammonia can be obtained in commercially paying quantities. Both the utilization of peat for producer gas and for producer gas and for the recovery of sulphate of ammonia are perfectly feasible with American peats. Although the work done on peat at the Survey experiment plant has been limited, it has been demonstrated that gas for power can be made easily from both Florida and Massachusetts peat."

Professor Davis, who has just issued jointly with Edson A. Bastin, a bulletin on peat is optimistic on the future of peat, yet he believes the development of the industry should be accompanied by great caution.

"The operation of a gas engine at the experiment plant on peat in one or two tests has shown that this fuel is but little inferior to many grades of soft coal now on the market and superior to some in the quantity of power gas produced," says Professor Davis. "I believe the day is coming soon when cities located near the peat bogs and away from the coal fields will obtain their power and light from peat. I understand that Florida is to have a power plant soon that will use peat as fuel and will transmit the electricity to Jacksonville."

In the development of this industry, however, it must be remembered that peat contains from 85 to 90 per cent. water as it comes from the bogs. All but 15 to 20 per cent. can be dried out by exposure of the peat to the air. In burning peat in gas producers to make power gas, this peat will burn successfully with 40 per cent. moisture, which is impossible in a furnace."

**METALLURGIST**, experienced in building and operating Mills Cyanide Plants, desires a change, married, references. Address, "Res-  
-iable" this office.

## Amatite ROOFING

Most roofings are made of only one layer, but Amatite is made in five layers. The bottom layer is wool felt, the next is real Coal Tar Pitch, the third is wool felt, the fourth is pitch again, into which is embedded the fifth layer, namely the mineral surface.

If the weather should, in the course of years, wear away the mineral surface and dispose of the layer of Pitch which is the most

waterproof substance on earth), it would still have to penetrate a layer of felt and another layer of composition and another layer of felt before the roof would leak.

It is easy to see why Amatite lasts so long when you realize how it is made.

That mineral surface requires no painting or coating whatever, and will take the brunt of the weather without renewal or attention or care.

Send for a sample of Amatite. It's free.

THE PATERSON MANUFACTURING CO., Ltd.  
Toronto, Montreal, Winnipeg, Vancouver, St. John, N.B., Halifax, N.S.

# The MINING MANUAL 1909

By WALTER R. SKINNER

**Price 21/- Post Free**

The Standard Reference Work on Mines

1,600 pages. In Demy 8vo.  
Handsomely bound in RED Cloth

A record of information concerning

**MINING COMPANIES (Gold, Diamond, Silver, Copper, Tin, Iron and other Mines, Collieries, Land and Exploration Concerns, &c.),**

Arranged in three sections—**AUSTRALASIAN, AFRICAN, MISCELLANEOUS,**

Preceded by **TABLES OF CRUSHINGS**, and followed by lists of

**DIRECTORS, SECRETARIES, MINING and CONSULTING ENGINEERS, and MINE MANAGERS,**

Their Names, Addresses and descriptions, and Names of the Companies with which they are connected, and a

**DICTIONARY OF MINING AND OTHER TERMS.**

**Mining Manual for 1909** contains particulars of over 3,500 Companies arranged in three sections, 450 Companies AUSTRALASIAN (including Western Australia, Queensland, Broken Hill, Deep Leads, New Zealand, and Tasmania; 1,000 AFRICAN including Transvaal, Cape Colony, Natal, Rhodesia, West Africa, Egypt); and 2,050 MISCELLANEOUS (including Siberia, Mexico, India, British Columbia, America, &c., and the Coal, Iron, and other mining concerns of the United Kingdom. The particulars given for each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with a full and complete consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts. Highest and lowest prices of the shares for the last four years, and the latest price. The three sections extend over 1,200 pages.

Crushing tables and Gold Outputs from the principal mines are given at the commencement of the volume, showing tons treated monthly, results obtained and yield per ton; also annual yields.

The List of Directors (7,000), Secretaries (1,750), Mining and Consulting Engineers and Mine Managers (1,300), include their addresses and descriptions and names of the Companies with which they are connected.

A complete Alphabetical Index containing the names of 5,320 Companies, including many useful items of reference, occupies 43 pages.

# NEW BOOKS on MINING, METALLURGY POWER GENERATION

## Principles of Mining

Valuation—Organization—Administration

Copper, Gold, Lead, Silver, Tin and Zinc

By Herbert C. Hoover, E. M.

200 pages, 6 x 9, illustrated, \$2.50 (10/6) net postpaid

Published April 1909

## A Manual of Underground Surveying

Loyal Wingate Trumbull, E. M.

Consulting Mining Engineer; formerly Professor of Mining, University of Wyoming; formerly United States Deputy Mineral Surveyor for Colorado

Over 250 pages, 6 x 9, fully illustrated, \$3.00 (12/6) net postpaid

## Mining Methods in Europe

By Lucius W. Mayer

Mining Engineer

170 pages, with many illustrations, \$2.50 (10/6) net, postpaid

This book places the latest information at the disposal of mining engineers and mining men. It is a most valuable piece of work and of the greatest importance to the mining man who seeks more economical and practical methods.

The illustrations from photographs taken in the mines by the author are a striking feature.

## The Study of Ore Deposits for the Practical Miner

With descriptions of Ore Minerals, Rock Minerals and Rocks.

A Guide to the Prospector.

By J. P. Wallace, M.D., E.M.

Member of the American Institute of Mining Engineers, and the Colorado Scientific Society

Over 350 pages, 6 x 9, with over 100 illustrations, cloth \$3.00 (12-6) net

Leather edition, pocket size, thin paper, \$3.50 (15s) net

## McNeill's Code

(1908 Edition)

\$13.00 net postpaid

This new edition does not contain a single code word appearing in the former edition. It is brand new, with a great many additions and is the best general code offered.

It covers the mining field with the greatest thoroughness and meets all requirements of all business. It is three times as large as the old edition.

The terminal index is embodied in this code.

## Notes on Metallurgical Mill Construction

Edited by Walter Renton Ingalls

256 pages, 6 x 9, cloth, \$2.00 (8/6) net postpaid

A New, One-Volume Edition of

## The Nature of Ore Deposits

By Dr. Richard Beek

Professor of Geology, Mining Academy, Freiberg

Translated and revised by Walter Harvey Weed

Formerly published in two volumes. Now issued in one volume.

\$6.00 (1£5s) net postpaid

## Millwrighting

By James F. Hobart, M. E.

400 pages, 6 x 9, fully illustrated, \$3.00 (12/6) net postpaid

(Published March 1909)

## Notes on Lead and Copper Smelting

Revised to November, 1908

By Hiram W. Hixon

162 pages, 6 x 9, \$3.00 postpaid

## Copper Mines of the World

By Walter Harvey Weed

Price \$4.00

## Principles of Copper Smelting

By Edward Dyer Peters

Price \$5.00

## The Metallurgy of Steel

By Bradley Stoughton

Price \$3.00

## The Manufacture and Properties of Iron and Steel

By Harry Huse Campbell

Price \$5.00

## A Manual of Fire Assaying

By Chas. H. Fulton

Price \$2.00

## Hydrometallurgy of Silver

By Ottokar Hoffman

Price \$4.00

## The Electric Furnace

By Alfred Stansfield

Price \$2.00

## Mining, Mineral and Geological Law

By Chas. H. Shamel

Price \$5.00

## Mine Timbering

By Sanders, Parlee, Macdonald and others

Price \$2.00

## Simple Mine Accounting

By David Wallace

Price \$1.00

## The Gas Engine

By Cecil P. Poole

Price \$1.00

## Gas Power

By F. E. Junge

Price \$5.00

## Producer Gas and Gas Producers

By S. S. Wyer

Price \$4.00

## Tulley's Handbook on Engineering

(Steam and Electrical)

By H. C. Tulley

Price \$3.50

## Motor Troubles

By E. B. Raymond

Price \$1.50

## Steam Turbines

By Lester G. French

Price \$3.00

## The Power Handbooks

Per volume \$1.00. Monographs on the following subjects:  
Shaft Governors Pumps Shafting, Pulleys and Belting  
Erecting Work Knocks and Kinks Engine-Room Chemistry  
Boilers Pipes and Piping Steam Turbines

## The Copper Handbook, Vol. VIII.

A Manual of the Copper Industry of the World

1,500 pages, 5¼ x 8½, price \$5.00

## Mineral Resources of Canada

140 pages, 7½ x 9½; 32 color engravings; mineral map of Canada

Price: paper \$1.00, cloth \$1.25

## The Dominion Coal Company

An Historical and Descriptive Brochure

By F. W. Gray

Price \$1.00

## IMPORTANT BOOKS IN PREPARATION

Volumes III and IV of

## Ore Dressing

By Robert H. Richards

Professor of Mining, Massachusetts Institute of Technology

2 Vols., 600 pages each, 6 x 9, fully illustrated, per Vol. \$5.00 (21/-)

net postpaid

(Scheduled for publication June 1909)

## Timbering and Mining

By W. H. Storms

6 x 9, fully illustrated, \$2.00 (8/6) net postpaid

(Price subject to change. Scheduled for publication June 1909)

## Electro-Magnetic Ore Separation

By C. Godfrey Gunther

6 x 9, fully illustrated, \$3.00 (12/6) net, postpaid

(Scheduled for publication May 1909)

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

**CANADA.—DEPARTMENT OF MINES.****Geological Survey****PUBLICATIONS**

The Geological Survey has published maps and reports dealing with a large part of Canada and with many local areas and special subjects.

**MARITIME PROVINCES**

The whole of Cape Breton and a large portion of the coal and gold fields of Nova Scotia have been reported upon and mapped on a scale of 1 mile to 1 inch. The remaining portions of the province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter provinces, mapped on a scale of 4 miles to 1 inch.

**QUEBEC**

Quebec, south of the St. Lawrence, has been reported upon and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the province north of the St. Lawrence are also available.

**ONTARIO**

A large part of the province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

**THE PRAIRIE PROVINCES**

Geological maps and reports have been issued covering the greater part of the provinces of Manitoba, Saskatchewan and Alberta.

**BRITISH COLUMBIA**

The southern portions of British Columbia, as well as other parts of the province, have been reported upon and mapped.

**YUKON**

Many of the important areas in the Yukon have been reported upon and mapped.

**THE NORTH-WEST TERRITORIES**

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to **THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.**

**THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:****NOVA SCOTIA**

- 1019 City of Halifax Sheet.  
1025 Waverley Sheet.

The above two sheets belong to the regular series of Nova Scotia map sheets on a scale of one mile to one inch. The first includes Halifax City and Harbour, the second the Waverley Gold District.

**ONTARIO**

1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

**BRITISH COLUMBIA**

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch, by W. H. Boyd.

NOTE.—Maps recently published may be had on linen cloth for use in the field at the price of 10c. per copy.

**REPORTS**

1072. Summary Report of the Operations of the Geological Survey for year 1908.

The Geological Survey, under certain limitations, will give information and advice upon subjects relating to general and economic geology. Mineral specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to **THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.**

# Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. FRANK COCHRANE,**

Minister of Lands, Forests and Mines,  
**Toronto, Canada.**

# PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unsurveyed territory, is open to prospecting.

**Miners' Certificates** good for a calendar year may be obtained by sending \$10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minimum being 40 acres in unsurveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of \$10.00 plus a yearly rental of \$1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed

territory may be purchased as a mining concession at the price of \$20.00 per acre if within 20 miles of a railway in a straight line, or \$10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

**The Hon. Minister of Colonization, Mines and Fisheries  
Quebec.**

## Going Prospecting?

When you are miles away from the nearest assay office, you are sure to run across some ore that looks good, yet you have no means of accurately determining its value. Then you will realize what

## Way's Pocket Smelters

will do for you. With the use of one of our outfits, you can make a test in five minutes and know what your ore contains. This test will only cost five cent, and if your ore contains values, you make your location then and there. If not you waste no more money on it. Better than waiting two weeks for returns from an assay office, and twenty times cheaper.

## BRITISH COLUMBIA

## The Mineral Province of Canada

has produced to the end of 1906, \$68,721,103 of Placer Gold; \$41,015,697 of Lode Gold, \$25,586,008 of Silver \$17,625,739 of Lead; \$35,546,578 of Copper; \$79,334,798 of Coal and Coke; and \$5,813,799 of Other Minerals or a total of **\$273,643,722**. The Mineral Production of the Province for 1906 was

**\$24,980,546**

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was \$5,579,03 the Lead Output 52,408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

**HON. MINISTER OF MINES**

**Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.**

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.  
Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 100,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

# OF CANADA

## Synopsis of Canadian North-West Mining Regulations

**COAL**—Coal mining rights may be leased for a period of 21 years at an annual rental of \$1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

**QUARTZ**—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is \$5.

At least \$100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee \$5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental \$10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds \$10,000.

**W. W. CORY, Deputy of the Minister of the Interior**

MANUFACTURERS OF

**High Explosives, Stumping Powder, Blasting and  
Sporting Powder, etc.  
Safety Fuse, Electrical Fuses, Batteries, and other  
Accessories.**

### NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

### "WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. It does not freeze, or rather, explodes with perfect efficiency when frozen and needs no thawing.

### "AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

### PERMITTED EXPLOSIVES for Coal Mines

**Nobel Monobel, Saxonite and Carbonite.**

A letter or telegram addressed to the head office or any of the following agencies will receive prompt attention.

COBALT      TORONTO      KENORA      WINNIPEG, MAN.

### What a User says of the Deister:

I have yours of the 7th inst. and am pleased to advise you that the results obtained at our Calvario mill with the Deister No. 3 Concentrating tables under my personal observation in treating the ores from the Carboncillo mine were not only satisfactory but have made it possible for us to treat one of our low grade ores at a good profit which heretofore could not be treated except at a loss. Ours is a gold-silver ore which was given to your table through an 80-mesh screen at the rate of about 12 tons per 24 hours. The table requires but very little attention and from our experience I am convinced that there is no machine now in use which could give us the results obtained. Neg. Minera "El Carboncillo y Anexas, S. A.," Zacualpam, Mexico. Yours truly, (Signed) A. C. Chabaud, Mgr.

# Behrend Concentration System

## Combination WET and DRY

A complete recovery from all slimes and minerals such as Graphite, Galena, Stibnite, Chalcopyrite, Tetrahedrite, Sylvanite, Molybdenite, Stephanite, Argentite, Ruby Silver and and Native Silver.

This system will make low grade deposits pay. Every mine having an eye to business should investigate this system which has the approval of leading mining authorities.

A completely equipped plant, including concentrators, crushers, rolls, etc., for testing purposes is located at address below. Forward a sample of your ore for preliminary test.

## Behrend Concentrators, Limited

48 Inspector Street, Montreal

## Underwood

The man who buys an Underwood typewriter does not bring the price into discussion.

He does not buy the Underwood on a price basis. He knows that to pay less is to get less—a great deal less.

He knows that in buying an Underwood he will get full value for every cent of the cost. And for this reason, Underwoods in Canada outnumber all other makes of typewriters combined.

## Amatite ROOFING

Most roofings are made of only *one layer*, but Amatite is made in *five layers*. The bottom layer is wool felt, the next is real Coal Tar Pitch, the third is wool felt, the fourth is pitch again, into which is embedded the fifth layer, namely the *mineral surface*.

If the weather should, in the course of years, wear away the mineral surface and dispose of the layer of Pitch (which is the most

waterproof substance on earth), it would still have to penetrate a layer of felt and another layer of composition and another layer of felt before the roof would leak.

It is easy to see why Amatite lasts so long when you realize how it is made.

That mineral surface requires no painting or coating whatever, and will take the brunt of the weather without renewal or attention or care.

Send for a sample of Amatite. It's free.

### THE STRIKE AT GLACE BAY.

That a foreign labour organization should be permitted to proselytize Canadian workmen by means of specious promises and baseless agitation is creditable neither to the good sense of the workmen themselves nor to the Canadian nation generally. But when foreign demagogues, in their desire to crush a Canadian labour party, incite some thousands of Canadian workmen to strike, then conditions have indeed become intolerable.

The Canadian Mining Journal has placed itself on record before now as being radically opposed to the encroachments of United States labour federations. The history of these bodies shows nothing that recommends either their aims or their methods. Their aims are inordinately selfish; their methods obnoxious to right-minded men. There is need for neither in this country.

From all that we can learn before going to press, it is probable that the United Mine Workers will be defeated in their attempts to cripple the Dominion Coal Company and to destroy the Provincial Workmen's Association. Their defeat will be due to the sane conduct of the P. W. A. members who refused to strike without honest cause. While we believe that this will quicken the P. W. A. into stronger life, it must be understood that the U. M. W. is a relentless and persistent enemy. Its resources are large, far larger than are those of the P. W. A. It never scruples to engender strife between capital and labour, and its policy is to precipitate strikes whenever possible. Its present action entails loss upon Canada as a whole, upon the Dominion Coal Company, and, most grievous of all, upon many hundreds of misguided workmen.

It is high time that Canadians recognized the absolute necessity of controlling their own affairs. The Lemieux Conciliation Act, an admirably designed piece of legislation, is intended to do away with the barbarous strike. It is a Canadian Act, drawn up for the benefit of Canada. If agitators from the United States, or from any other country, are allowed to foment trouble, the Conciliation Act becomes a superfluity. We heartily approve of the refusal of the Dominion Coal Company to treat with the U. M. W. In this it has established a precedent that will, we sincerely hope, be followed by all Canadian companies. But we would go further than this. To give to foreigners the right to invoke the interposition of a Conciliation Board is to invite constant trouble. This privilege must be confined to Canadian citizens. For their protection the Act was formulated.

Canada looks after the interests of the foreigner within her gates as well as, if not better than, most

other countries. But her duty is first to protect her own citizens. Canadian labour can best be protected by measures that will eradicate the imported agitator who makes the Conciliation Act a stumbling-block and arbitration a vain thing.

Our newly appointed Minister of Labour could signalize his advent to office most fittingly by restricting the application of the Act to Canadians.

The Dominion Coal Company never had a strike, never erected fences for protection, never called in the police until the U. M. W. made it appearance in Nova Scotia.

### ASBESTOS ONCE AGAIN.

Quebec asbestos mining is suffering more than its fair share of promotion. On the heels of the huge Amalgamated flotation comes news of a new "merger"—the Black Lake Consolidated Asbestos Company, capitalized at \$5,000,000. The holdings of the latter concern cover some 5,000 acres of territory, only a small fraction of which is developed. Not one of the properties has been worked at a profit. Further, development so far has given little indication that the properties are valuable.

We believe that shares in neither Amalgamated nor Consolidated will find a ready market in this country. If they are placed successfully in London it will be due to the ignorance of trans-Atlantic investors as to the condition of affairs in Quebec.

The asbestos industry of Quebec is, per se, a vigorous, sound, and progressive branch of mining. Until recently, Canadian producers have been able practically to control the market. As mentioned before, however, Russia is becoming a formidable competitor. South Africa will sooner or later enter the field with a high-grade article. Other countries will also take their quota of the trade.

Quebec producers will continue pre-eminent for some time. They have reached a stage of development and equipment that new districts cannot approach for several years. We hope that Quebec will always maintain a leading position. But it is futile to ignore the developments that are taking place in other lands; and it is criminal for promoters to discount the future with no regard to the inevitable competition of foreign producers.

It is justifiable, then, to look upon the present asbestos flotations as untimely, unprofitable, and inflated to a degree that will do positive and immediate injury to the industry. Consolidation is often wise. Often it is necessary to the reduction of working and administrative costs. We do not believe that working costs in the Quebec asbestos mines will be lowered one cent under the control of the new corporation. We know that fixed charges will be very considerably increased. The new organizations have been called into being not to cheapen production, but to line the pockets

of promoters. Not consolidation, but inflation, is the keynote of the Amalgamated Asbestos Corporation and of the Black Lake Consolidated.

It is pertinent to add here that within the past quarter there has been a notable reduction in the selling price of all grades of asbestos. Overproduction, a deliberate preliminary to promotion, has surfeited the market. Information has reached us from producers and from consumers signifying that the drop has been heavy, in some instances amounting to more than 25 per cent., a reduction that will wipe out all profits. Production is being increased, despite this falling market. The object of this is clear. It is literally manipulation to aid in the disposal of Amalgamated shares, by giving a false colour of activity.

### SCOTCH OIL-SHALE COMPANIES.

The present condition and future prospects of mining companies operating the oil-shale deposits of Scotland are noteworthy. Of late the large possibilities of the New Brunswick oil-shales have received wide advertisement. It is probable, indeed, that, ere long, capital will be supplied for the purpose of mining these shales and marketing their diversified products. The Scotch oil-shale industry, as it stands to-day, is a monument of persistent, intelligent, and successful endeavour. Its history will afford guidance and encouragement to those who undertake the exploitation of the New Brunswick deposits.

The past financial year was one of general prosperity for the five companies engaged in the Scotch mineral oil trade. The lower prices obtained for their products were offset by lessened cost of production, due largely to cheaper coal and lower wages. Thus, in spite of keener competition on the part of the Standard Oil Company, aggregate profits amounted to £380,207, as against £372,343 for the preceding year. In addition to profits earned, the plants of the various companies have been enlarged and improved.

The strong financial position of the leading concern, the Pumpherston Company, is noteworthy. Although there was a slight falling off in its profits last year, yet it has been able to maintain its dividend of 50 per cent., to carry forward a larger balance, and to write off the sum of £41,758, the amount expended in improvements. This company has built up a reserve fund of £100,000, and a fire insurance fund of £10,000.

The other companies report increased profits and growing reserves. In every case ample amounts have been allotted to cover depreciation and to build up reserves.

Heretofore, the oil companies have relied upon wholesale dealers to market the oil. One company, the Oakbank, is now attempting to undertake its own marketing. The experiment, if successful, will lead to the organization of a central selling agency that will market the products of all the companies.

The immediate future is clouded by the renewed hostility of the Standard Oil Company, a recent reduction of ½d. per pound in the price of paraffin wax, a drop that will have to be met by the Scotch producers. As paraffin wax is their principal source of profits, the reduction is most unwelcome. On the whole, however, the Scotch companies appear to be entirely able to meet competition. On the other hand, there is little reason to believe that the present rate of dividends can be maintained for an indefinite period.

### A MIGRATING FAKIR.

Last year we were constantly being regaled with blood-curdling stories about what a certain Mr. J. H. Brown, expert, was to do at the Trout Lake Smelter. Between promise and performance there is a vast gulf fixed in Mr. Brown's case. Having exhausted the patience of his shareholders and the resources of his own vocabulary, Mr. Brown looked round for pastures fresh. North Sydney, Nova Scotia, an inoffensive town that has much quiet ambition, appealed to Mr. Brown. Its emerald hue was soothing to his eye. So Brown polished up his intimate "John Hayes Hammond" anecdotes, and blew into North Sydney.

The man who designedly imposes upon a trusting town council is a heartless wretch. Mr. Brown did impose upon North Sydney. The councillors opened their arms and Mr. Brown did the rest. Strange to relate, he got no cash out of his victims—merely concessions of land and certain immunities. But the way in which he mesmerized the local papers was sinful—only less sinful than the stories that he told of his dear friends, Cecil Rhodes and "John" Hammond.

Perhaps Mr. Brown will have vamoosed before this reaches his unregenerate eye. There is in every Nova Scotian community a leavening sense of humour that would prove Brown's undoing. Only it is not easily aroused. But it will be safer for Mr. Brown to purchase a ticket—single fare—for some Pacific port at a very early date.

Fie, fie, Mr. Brown! robbing North Sydney is worse than striking a woman!

### INVESTMENT.

The ideal conditions for mining investment are not those that obtain most largely in Canada. Canadians are yet too anxious to make "turnovers" and "rake-offs" and "commissions." Cobalt is answerable for a good deal of this.

Obvious facts are consistently overlooked. Before a mining prospect can be priced, its future earning capacity as a mine must be indicated. Mining costs are of prime importance; but the net profit on each ton of ore is the vital consideration. Every cent spent in prospecting, in developing, in advertising, in commissions, must ultimately come out of the mine.

Hence the prospecting and development stage is precisely the stage at which expenditure must be most carefully controlled. Otherwise a cumulation millstone is placed on the neck of the venture.

Mining investment is not the purchase of undeveloped property. That is mining venture. The outlay of money to develop known ore bodies, to provide equipment for a mine, and to establish market connections, is investment.

With proper precautions there is no cleaner, more attractive, and more remunerative form of investment, and legitimate opportunities exist all over Canada.

There are many objections to syndicated or incorporated enterprises. Owing to prevalent misconceptions, the average director or syndicate member may always be counted upon to kick at the critical moment when more money is needed to make his mine productive. Only experience will remedy this.

The ideal condition is provided when one or two keen business men employ a competent engineer to develop for them a mineral deposit at a minimum of cost, and when development has proved successful come forward with ample working capital. In a case of this kind no undue risk need be taken, operations may be dropped at any time without serious loss, and the enterprise is pushed only if success is practically assured.

### ROYAL RECOGNITION.

A significant incident is mentioned in a late cable from England. On the occasion of laying the foundation stone of the new buildings of the Imperial College of Science and Technology at South Kensington, King Edward emphasized the supreme importance of technical education. The King referred especially to the function of specialized scientific instruction in fitting England to cope with her industrial competitors, and signified his belief that herein lay her best safeguard in the future.

This is perhaps the most pregnant feature of the wave of industrial change and reform that has been sweeping over Great Britain. Better than warships, more effective than all the artillery in the world, is the protecting power of industrial supremacy. Germany is industrially efficient—more efficient than most people know, less efficient than her panegyrists would have us believe. Commercially, the United States is enormously rich, enterprising, active, and wasteful. Nature has endowed her with marvellous resources. These resources have been exploited recklessly.

Great Britain, as the keystone of the British Federation, must become the developing agent for the outlying members of the Empire. Great Britain has the money, the Empire has the men. Direction and co-operation are needed.

Technically trained men, more especially trained mining engineers, are the missionaries of industrial development. Their work calls them all over the world.

The results of their work will always be the principal factor in fusing and uniting the British Empire.

England is equipping herself to train her youth. The enthusiasm manifested by King Edward is symbolic of the ardent ambition that is permeating the nation and the Empire. We must make ourselves fit if we are to survive in the race.

### THE NEW TIPPLE AT MICHEL.

The new tippie erected for the Crow's Nest Pass Coal Company at Michel, B.C., is worthy of comment. It was working within six months from the date on which the contract was signed. It is now, eleven months from that date, completed.

Although the plant was assembled and erected 3,000 miles from the place of manufacture, and the construction done during the winter season, no delay occurred. As the tippie has a capacity of 1,000 tons of run-of-mine coal per hour, the largest capacity of any single tippie on the continent, its rapid completion is somewhat of an engineering feat.

The tippie structure is of steel throughout. Approximately 600 feet long, it crosses the C. P. R. right of way by a clear span of 105 feet. The equipment includes a self-dumping car haulage system. The tracks are superposed, the haul utilizing the upper and lower runway principle of the bucket conveyor. The driving mechanism is practically identical with that utilized in conveyors, the mine cars taking the place of buckets. With the superposed track system the tippie requires only width for one track and walkways on both sides. Thus through the machinery section it is only 14 feet wide, and 12 feet wide at the approaches.

The erection of this tippie, which is apparently the last word in modern tippie construction, will set a standard of excellence for the Western coal mines. We congratulate the Crow's Nest Pass Coal Company on the prevision that has animated this progressive step.

### VON HAGEN.

We shall consider it a favour if any of our readers who have been induced to purchase stock in the concerns promoted by "Dr." Hugo Von Hagen will send us, confidentially or otherwise, a clear statement of their transactions. "Dr." Von Hagen is a cheap charlatan, and his mining schemes are fraudulent. The Canadian Mining Journal wishes to secure the specific evidence that is necessary to institute criminal proceedings against Von Hagen. Owners of shares in the Great Northern Coal Company, the Northern Coal Company, the Kent Coal Company or the Maritime Coal Company (New Brunswick) will be doing the country a service if they aid us in putting an end to Von Hagen's career.

### EDITORIAL NOTES.

In 1907 the deaths resulting from falls of roofs and coal in Westphalian collieries numbered 223. The death-rate was 0.953 per 1,000 persons employed. The average death-rate for the period 1885-898 was 1.170; for the period 1899-1907, 0.984.

Our contemporary, The Mining Journal, has decided to decrease the size of its page. No one will question the wisdom of this decision. Notwithstanding the valuable and interesting character of the pages of our London contemporary, the leaves are irritatingly hard to turn, and copies do not fit into any ordinary scheme of filing. Therefore the change will be welcomed.

The statement made by the promoters of the Black Lake Consolidated Asbestos Company to the effect that the new concern will have "friendly relations" with the Amalgamated Asbestos Corporation, has been contradicted unqualifiedly by Mr. E. B. Greenshields. It is unfortunate that a like regard for exact truth has not been evident in the matter published by Amalgamated itself.

Through error the review of Skinner's "Mining Manual" for the year 1909 was given as for the year 1908 in a recent number of the Canadian Mining Journal. The 1909 edition of this invaluable handbook was published on February 8, 1909. This was the edition reviewed. We may add that, for office reference, this volume is in constant requisition. In fact, it is practically impossible to get along without it.

Through the efforts of the West African Chamber of Mines during the past twelve months, the railway rates on the Gold Coast Government Railway were reduced by about 30 per cent. These reductions covered nearly all the important items that went to make up the supplies in constant use by the mining companies. From the Elder-Dempster Line, a shipping company that enjoys a monopoly of West African trade, no concessions were obtained.

At the Robinson mine, on the Rand, a large new mill engine is being installed. It will be of 2,000 hp. Its arrangement is novel. The high and low pressure cylinders, which are 33 inches and 66 inches diameter respectively, by 54 inches stroke, are not coupled in tandem. The crank shaft is coupled direct to the line shafting of the battery. A 1,350 kilowatt A. C. generator is placed on this shafting, so that when electric power is supplied by either of the new power supply companies this generator will be used as a motor, and the mill engine will be disconnected, at the coupling provided, and used as a standby. For the concrete foundations of the engine an excavation into the rock has been made, and about 16 feet of concrete will be put in place.

# IN THE MICHIGAN COPPER COUNTRY.

Written specially for the Canadian Mining Journal by R. E. Hore.

The copper deposits of Michigan present many points of interest. The profits derived from mining operations have been enormous, and in addition to making several great fortunes, are directly or indirectly the support of some thousands of people. The peculiar nature of the deposits, their great extent, the depths to which they have been worked, the heavy machinery

Calumet and Hecla Mines, Calumet—Looking north along one of the lines of shafts.

demanding, are some of many features which attract the attention of mining men. The extensive mining operations have afforded unusual opportunities for accurate determination of the character of the ore deposits.

In Canada there are known to be large areas of rocks similar to the copper-bearing series. In the greater number are on Keweenaw Point, the others on the extension of the Copper Range westward. The western group has not reached the importance of those in the vicinity of Calumet and Houghton.

Lake Nipigon region and at intervals along the north shore of Lake Superior there are formations which have been correlated with those of Keweenaw Point. Explorers of the far north have described copper deposits in rocks which are apparently identical with the Keweenawan. The information obtained in the ex-

Quincy Mine, Hancock—A new shaft-house; concrete and steel

tensive development of Michigan deposits will be invaluable to those who exploit similar resources in Canada.

## Location and Nature of Deposits.

The accompanying map (Fig. 1) shows the location of the chief mines of the Keeweenaw Range. The

The copper-bearing series is largely made up of lava flows, with which are interbedded some conglomerates and sandstones. The sedimentary rocks form only six or seven per cent. of the total thickness of the Keweenawan. The beds dip under Lake Superior, as indicated in Fig. 2. At Calumet the dip is 38 to 41 degrees, at Houghton about 56 degrees.

The tops of the numerous lava flows are generally amygdaloidal, and the bottoms show similar structures much less pronounced. Vesicular cavities have been filled with secondary minerals, calcite, quartz, and hydrous silicates being the most common. In some

"Blow off," Victoria Mine, on Ontonagon River. The Victoria is one of the pioneers to use hydraulic compressed air. The photo shows a column of water and air escaping from twelve inch pipe, shooting over one hundred feet above the opening.

cases the secondary filling is native copper, and this is one of the most important types of deposits—copper "amygdaloid." The "Kearsarge amygdaloid" is a very extensive lode of this nature.

The conglomerates are made up largely of material are very abundant in some of the beds. In some cases similar to the lava flows, but reddish felsite pebbles part of the cementing material is native copper, and this has afforded the richest of the ore deposits—

"copper conglomerate." The "Calumet conglomerate" is a good example of this class.

A third class of deposit is that of veins traversing the bedded rocks. These are yielding very little of the present output.

In working the conglomerates, owing to the loose nature of the material, a large amount of worthless rock has to be mined with the pay rock. The trap underlying amygdaloidal beds is of dense, compact character, and need not be removed. Consequently an

Dollar Bay Smelter—Showing piles of ingots ready for shipment.

"amygdaloid" lode may be mined with greater profit than a lode of same values in a conglomerate bed.

While a general plan like Fig. 2 indicates simple structure in the deposits, the workings are complicated by the occurrence of innumerable faults and changes in dip of the beds.

The great extent of the lodes is indicated by long lines of shaft-houses, which in some cases extend great distances. The "Kearsarge amygdaloid" is cupriferous in paying quantities for eleven miles, although everywhere the copper is irregularly distributed. The inclined beds have been followed down in some mines for eight or nine hundred feet. Some vertical shafts, including the famous "Tamarack" and C. & H. "Red Jacket," which cut obliquely across the beds, are one mile in depth.

Dollar Bay Smelter—Showing methods of hauling ingots from casting machine to dock.

While copper is found at these great depths, the deposits are as a rule less rich than those nearer the surface. Mining at the lowest levels has in many cases been carried on with but little profit, and at present the amount of ore which is raised from them is very small.

It is well known that the temperature in these lower levels is high enough to cause inconvenience to work-

men, even when scantily clad. The loss of values, however, has apparently been the only reason for the discontinuance of the work at great depths.

The low price of copper has seriously affected the mining of lower grade lodes in the last two years. Some of the companies operating on lodes yielding a very slight margin of profit had to close down. Others are drawing on their reserves of capital to further explore their deposits, while they wait for the price to rise again. Thousands of feet of diamond drilling has

Dollar Bay Smelter—Showing "mass" copper, which is brought directly from mine to smelter. Comparatively little of the copper mined is in such large nuggets.

been done, thereby adding much to the knowledge of the deposits, and making a few important discoveries.

#### The Mines and the Geological Survey.

Iron and copper are the chief of the metals mined in Michigan. The iron deposits are largely controlled by one corporation that has a number of geologists in its employ. The copper mines are owned by a large number of independent companies, large and small, and these find a connecting link in the State Geological Survey. The survey maintains a branch office at Houghton in the midst of the mining activities. State Geologist Lane is ever busy examining mine workings and drill cores in the endeavor to correlate beds and find lost lodes. From the information and the facilities for per-

Hauling concentrates four miles to railroad. Steep hills materially increase transportation expenses of some of the mines.

sonal examination given him by intelligent, far-seeing mine managers he accumulates a host of data useful both to miner and to pure science.

Director Brock, of the Geological Survey, is suffering from a diphtheritic sore throat. He has been in hospital for a week. The case is not serious.

# Annual Report of the Provincial Mineralogist for the Year Ending 31st December, 1908, Being an Account of Mining Operations for Gold, Coal, Etc., in the Province of British Columbia.

Like its predecessors, the Annual Report of the British Columbia Bureau of Mines ranks easily as the most complete and best arranged provincial publication.

## Progress of Mining.

The value of the mineral products of the Province for the year 1908 amounts to \$23,851,277, which is less than that of 1907 and 1906, but still considerably greater than that of any previous year.

The tonnage of ore mined in 1908 was the largest on record, and the average assay of the ore was slightly greater than that of 1907. But the average market value of the various metals for the year was much

mines, of which 59 shipped more than 100 during the year. The total number of men employed in metalliferous mines was 3,537—1,089 above ground and 2,448 below. This total is less than the actual number of men employed. A mine employing 12 men for four months is credited with four men for twelve months, and so on.

In seven mining districts, Coast and Cassiar, East Kootenay, Slokan, Nelson, Trail Creek, Lardeau and Trout Lake, and Bounday, there were 102 non-shipping mines, with a total of 157 men employed.

## Coal.

Nearly all of the coal mined during the year was produced by three companies—the Crow's Nest Pass Coal Co. in East Kootenay, and the Wellington Colliery Co. and the Western Fuel Co. on Vancouver Island. Several new collieries are soon to become producers.

Probably the most important of these new collieries is that of the Hosmer Mines, Ltd., at Hosmer, a few miles north of Fernie, in East Kootenay. The seams being opened up here are supposed to be the same series as those worked by the Crow's Nest Pass Coal Co. The plant is most extensive and modern. The company is an offshoot of the Canadian Pacific Railway.

In the same section of East Kootenay the Corbin colliery, at Corbin, on McGillivray Creek, has just been opened up. The company is associated with powerful railway interests.

In the Coast district, the new colliery of the Nicola Valley Coal & Coke Co. shipped 26,227 tons of coal during 1908. This production was limited by the market that the C. P. R. freight rates would allow it to reach, rather than by the capacity of the mines. The adjoining colliery of the Diamond Vale Colliery Co. produced 3,011 tons of coal. It is still in the development stage.

On Vancouver Island, the South Wellington Coal Mines, Ltd., near Nanaimo, and the Gilfillan Colliery at Wellington, produced small quantities of coal.

The gross output of the coal mines of the Province for the year 1908 was 2,109,387 long tons, and as 12,820 tons were taken from stock, it makes the total quantity of coal disposed of during the year 2,122,207 tons. Of this gross amount, 918,872 tons were sold for consumption in Canada; 567,274 tons were exported to the United States, and 29,883 tons were exported to other countries; making a total of 1,516,029 tons of coal sold.

In addition to the sales, 431,538 tons of coal were used in making coke, and 174,640 tons were consumed under colliery boilers.

From the 431,538 tons of coal, 247,399 long tons of coke were produced. - Of this amount 768 tons were added to stock. The net coke sales were thus 246,631 tons—209,317 tons sold for consumption in Canada, and 37,319 tons for consumption in the United States.

**Coast Collieries.**—In 1908 the coast collieries mined 1,226,182 tons of coal, and 13,921 tons were taken from stock, a total of 1,240,103 tons, distributed as follows:

Canada Zinc Co.'s Plant, Nelson, B.C.

lower. The effect of this drop in market price meant a decrease of \$3,966,826 in the total value of ore mined.

The tonnage of ore mined during the year 1908, exclusive of coal, was 2,083,606 tons, an increase over the preceding year of 279,492 tons, or 15.5 per cent.

This total tonnage was produced by the various districts in the following proportions:—

|                               |      |                     |
|-------------------------------|------|---------------------|
| Boundary . . . . .            | 71.6 | percentage of total |
| Rossland . . . . .            | 14.5 | " "                 |
| Fort Steele . . . . .         | 7.9  | " "                 |
| Coast District . . . . .      | 1.7  | " "                 |
| All other districts . . . . . | 4.3  | " "                 |

Boundary district shipped ore to the extent of 1,491,063 tons. Next came Trail division with 302,419 tons to its credit, and Fort Steele with 165,313 tons. All other tonnage records were individually below 50,000 tons. There were, all together, 108 shipping

Sold as coal in Canada,..... 717,964 tons  
 Sold as coal in the United States, 300,445 tons  
 Sold as coal in other countries,.. 29,883 tons

Total sold as coal, ..... 1,048,292 tons  
 Used under companies' boilers, 120,523 tons  
 Used in making coke, ..... 71,288 tons

1240,103 tons

export sales to the United States, which in 1908 show a dropping off of 59,221 tons, or about 13.7 per cent., as compared with 1907, while, as compared with 1906, the decrease is still greater, amounting to 132,738 tons. These decreased sales are accounted for by the use of oil fuel in California, and, to a less extent, by the importation of coal from Japan.

The Wellington Colliery Co., the only coke producer, made 12,530 tons of coke, of which only 6,022 tons were

As compared with 1907, there is a decrease of 31,453 tons, 2.9 per cent., in the sales of the coast collieries.

The consumption of coal in that portion of British Columbia served by the coast collieries shows in 1908 an increase of 19,923 tons, equal to 2.85 per cent. The amount sold for export to countries other than the United States, shows an increase of 35.6 per cent.

The decrease seems therefore to be confined to the

sold. Of this amount, British Columbia took 2,904 tons, the United States 3,118 tons, and 6,508 tons were added to stock. These figures show a great falling off in the consumption of coke in the coast section.

**East Kootenay Coal Field.**—In this field the Crow's Nest Pass coal Co. produced 876,467 tons of coal, of which 359,703 tons were used in making 234,098 tons of coke.

Hosmer Mines produced 2,627 tons of coal and 771 tons of coke; while the Corbin Coal and Coke Co. produced 4,111 tons of coal and no coke.

The gross production of the district was 883,205 tons of coal, of which 1,101 tons were still in stock at the end of the year, making the amount of coal dis-

Steel Tippie, Hosmer Mines, Limited, Hosmer, E. K.

tributed 882,109 tons. Of this amount 360,250 tons were used in making 234,869 tons of coke.

Distribution of coal was as follows:

|                            |              |
|----------------------------|--------------|
| Sold in Canada.....        | 200,908 tons |
| Sold in United States..... | 266,829 tons |

|                                  |              |
|----------------------------------|--------------|
| Total sold as coal.....          | 467,737 tons |
| Used in making coke.....         | 360,250 tons |
| Used under colliery boilers..... | 54,117 tons  |

882,104 tons

The total coke sales were made up of the 234,869 tons of coke produced and 5,740 tons taken from stock. 206,413 tons were sold for consumption in Canada, 34,196 tons for export to the United States.

The coke production shows an increase of 28,328 tons, or 13.7 per cent., as compared with the previous year. The total coke sales show an increase of 39,732 tons, or 19.7 per cent.; the coke sales in Canada show an increase of 64,426 tons, or 46.4 per cent.; but the coke sales to the United States show a decrease of 25,694 tons, or 42.9 per cent.

The Fernie fire and radical changes in the system of mine development at the collieries of the Crow's Nest Pass Co. retarded that company's output temporarily. In future, however, the output will be more regular and the mines safer for the workmen.

### Gold.

**Placer Gold.**—The production of placer gold in 1908 was about \$647,000, a decrease of \$181,000, or 21.8 per cent., as compared with 1907. The principal loss was recorded in the Atlin District, where this year's production was \$203,000, only half what it was the year before. In Atlin, the Atlin Consolidated Mining Company failed to operate, and the Pine Creek Power Company was enlarging its ditch, and therefore did no gravel-washing.

The Cariboo District—including Barkerville and Quesnel sections—held its own, and produced over half the placer output of the Province.

Dredging for gold has not been successful; the inland dredges at Atlin have been abandoned, and only a small amount of gold was recovered from the dredging done at Lillooet and Yale on the Lower Fraser River.

**Gold from Lode Mining.**—The value of gold produced from lode mining during the year 1908 was \$5,282,880, an increase of some \$1,227,860, or over 30 per cent. This large increase was principally due to Rossland, which produced this year \$986,806, or 50 per cent. more gold than in 1907, partly by increased tonnage, but chiefly through increased value of ores.

The Boundary District showed an increase in gold output of \$213,583, or about 12.7 per cent. Here the tonnage mined was 27 per cent. greater than in 1907, and the average tenor of ore smelted was slightly lower than in 1907.

Nelson District shows an increase of \$82,535, attributable chiefly to the activity of the gold-bearing properties in Sheep Creek camp, in the vicinity of Salmo.

The only district reporting a large deficit in lode gold output was the Coast District, which produced \$58,744 less gold than in previous years.

About 87.5 of the lode gold output of the Province was recovered from the smelting of copper-bearing ores. The remaining 12.5 per cent. was recovered by stamp milling, etc.

### Silver.

The total amount of silver produced in the Province during the year 1908 was 2,631,389 ounces, valued at \$1,321,483, a decrease of 114,059 ounces, and of \$382,342 in value.

The average market price of silver in 1908 was 11.84

Electro-Thermic Furnace, Canada Zinc Co., Nelson, B.C.

cents per ounce lower than in 1907, which accounts for \$311,556 of the decrease.

About 77 per cent. of the total silver output was obtained from ores in which it was found associated with lead, the remainder being found chiefly in conjunction with copper-bearing ores.

The Slocan District supplied about 50 per cent. of

the total Provincial output, and the Fort Steele Division about 24 per cent., all from argentiferous galena.

The lead production of the Province was 43,195,733 pounds, having a market value of \$1,632,799. As compared with 1907 this is less by 4,542,970 pounds, or 9.5 per cent. The decrease in value is \$658,659, or 29 per cent.

The average market price for the year 1908 was a little more than one cent per pound lower than during 1907.

|                               |                        |
|-------------------------------|------------------------|
| Fort Steel M. D. produced.... | 30,204,788 lbs.=69.9%  |
| Slocan .....                  | 6,572,268 lbs.=15.2%   |
| Ainsworth .....               | 4,790,216 lbs.=11.1%   |
| Trout Lake .....              | 873,860 lbs.= 2.1%     |
| Nelson .....                  | 345,424 lbs.= 0.8%     |
| All others .....              | 409,177 lbs.= 0.9%     |
|                               | <hr/>                  |
|                               | 43,195,733      100.00 |

### Copper.

The output of copper in 1908 was 47,274,614 pounds, having a gross market value of \$6,240,249. This is the largest output ever made. It exceeds last year's production by 6,441,894 pounds, or about 15.7 per cent. The lower average market value of the metal for the year 1908 reduced the market value by \$1,926,295, or 23.5 per cent., as compared with 1907.

The average market price for the year was 6.8 cents a pound less than it was in 1907, a direct loss to the producers of \$3,214,674.

The great increase in production was made in the Boundary District, due to the increased tonnage of ore mined.

In the Coast districts a decrease of 1,760,630 pounds, or nearly 50 per cent., was reported.

This table of production gives the output by districts:—

|                                |                        |
|--------------------------------|------------------------|
| Yale (Boundary) District ..... | 40,181,790 lbs.=85.0%  |
| Rossland .....                 | 5,042,244 lbs.=10.7%   |
| Coast and Cassiar .....        | 1,997,337 lbs.= 4.2%   |
| Yale-Kamloops .....            | .....                  |
| Nelson .....                   | 53,243 lbs.= 0.1%      |
| Other districts .....          | .....                  |
|                                | <hr/>                  |
|                                | 47,274,614      100.00 |

The average assays of the copper ores of the various camps, based upon the copper recovered, were as follows: Boundary, 1.35%; Coast, 2.87%, and Rossland, 0.834%.

### Other Minerals.

There was no iron ore shipped during 1908. Only a small quantity of zinc ore was shipped. The favourable final ruling of the U. S. Treasury Board, which will admit zinc ore free into the United States, will mean increased shipments. The saving of platinum from alluvial gold washings is neglected on account of the high cost of operations.

Building stone quarries are few and far between. This industry has great possibilities. Marble, red brick, fire brick and fire clay, lime-silica brick, lime, and cement are attracting more attention.

Further notice of these commodities will appear in a later issue of the Canadian Mining Journal.

### STAR VS. WHITE.

Information has lately been received in British Columbia from London, England, to the effect that leave to appeal to the Privy Council against the decision of the Supreme Court of Canada sustaining the judgment of the Full Court of British Columbia in favor of the Star Mining and Milling Company, has been refused the defendant company, the Byron N. White Company.

This action, long referred to as the Star vs. White case, was one respecting the extra-lateral or apex right of the well-known Slocan-Star silver-lead mine near Sandon, Slocan District, British Columbia, owned by the Byron N. White Company, of Milwaukee, Wisconsin, U.S.A., of which company Byron N. White, of Spokane, Washington, is president and general manager.

The Slocan-Star group comprises a number of mineral claims having a total area of about 500 acres. The Star Mining and Milling Company, of which John M. Harris is president, owns some adjoining mining property, from which the Slocan Star took a quantity of ore under circumstances stated below.

The action was commenced in July, 1901, at Nelson, B.C., by Mr. Harris in the name of the Star Mining and Milling Company. He sued for the value of all ore taken out of the Heber Fraction and Rabbit Paw mineral claims by the Slocan Star management, and for a declaration of title and an injunction. The action has since been the subject of a number of appeals, both interlocutory and final, and has been before different courts in British Columbia and Ottawa about 74 days in all.

The first trial was held at Nelson, in February and March, 1904, and lasted 23 days. At that trial W. J. Elmendorf and Professor Parks, both prominent mining engineers, of Spokane, were the chief expert witnesses for the White Company, while Frank L. Sizer and R. M. Atwater, also engineers of high standing, of Helena, Montana, gave testimony for the Star Company.

The defendant company admitted its trespass upon the property of the plaintiff, but endeavored to justify it under its apex rights, claiming that it followed downward from its apex to the ore in question. The plaintiff on the contrary, contended that near the boundary of its property the White Company encountered a fault fissure and lost the Slocan Star vein, hence the continuity of its vein was destroyed; also, that the apex claimed by the White Company was the apex of the barren fault fissure and not of the Slocan Star vein, and did not connect with the ore in question. In opposition to this contention by the plaintiff company, the White Company maintained that the whole workings were in its vein that is, the Slocan Star vein. Many samples, models and plans were filed in evidence by both parties to the suit.

The trial was not at that time concluded, but was adjourned to allow of the conflicting theories being put to test by experimental work on the ground. S. F. Parrish, then general manager of the Le Roi mine, Rossland, was chosen by the court to superintend the work ordered, but by reason of his illness another mining engineer was, after many months' delay, required. The

defendant company opposed such a substitute appointment and, through its counsel, urged the Chief Justice to make a personal examination of the mine workings in question. After having examined the mine for himself, the Chief Justice refused to permit any experimental work to be done, as had previously been arranged for at the request of the plaintiff, and directed that the trial be proceeded with, which was done at Nelson, in July, 1905. Much evidence was taken, including that of S. S. Fowler, M.E., of Nelson, for the plaintiff company. Counsel for Mr. Harris pressed their motion for test work, but this motion was dismissed, and in November, 1905, the Chief Justice gave judgment in favor of the defendant, the Byron N. White Company. This was appealed, with the result that, in November, at Vancouver, the Full Court ordered that the test work applied for by the Star Company be done under the direction of court.

W. E. Zwicky, manager of the Rambler-Cariboo Mines, Ltd., of Kaslo, was selected to supervise this work, which resulted favorably for the Star Company. Upon this, counsel for the plaintiff company contended that every test made decisively established the correctness of the theories advanced by Mr. Harris' expert witnesses, and two judges of the court decided in favor of Mr. Harris, while one held an opposite opinion. So Mr. Harris' appeal against the judgment of the Chief Justice was allowed. Thereafter the White Company appealed to the Supreme Court of Canada, and this appeal was heard in Ottawa in October, 1908. The result was that on February 13, 1909, the unanimous judgment of that court was delivered, dismissing the appeal of the White Company and sustaining the judgment of the Full Court of British Columbia, which latter court had reversed the judgment of Chief Justice Hunter at the trial.

The position now is that John M. Harris, who is also largely interested in the valuable Reco mine, near Sandon, has a judgment giving him a clear title to the Weber Fraction and Rabbit Paw mineral claims, a perpetual injunction against the defendant's mining on his property, full damages for all ore taken from these claims and all costs of trials and appeals.

The refusal of the Judicial Committee of the Imperial Privy Council to grant the Byron N. White Company leave to appeal to the highest court in the Empire may be regarded as the last act in one of the most important, hardest fought, and most costly mining trials ever carried through in British Columbia. Its final conclusion will be welcomed in Sandon camp if it leads to a resumption of work on a similar scale to that of the old concentrating mill was one of the chief sources of commercial prosperity to the town of Sandon.

While many will heartily sympathize with Mr. Byron White in his eventual defeat after a long fight for earlier years when the payroll of the Slocan Star mine that he regarded as his rights, there is the consolation of knowing that he has been fortunate in another direction, in the discovery on another part of the Slocan Star group last year of the continuation of a fine shoot of ore first opened on the Richmond-Eureka property, which discovery indicates that the Slocan Star possesses probably \$500,000 worth of silver-lead ore of shipping

grade, the existence of which on the property was not previously known.

### SHEEP CREEK, B.C.

During the year 1908 over 200 new locations were made during the summer months in the Sheep Creek camp, Nelson Mining District, B.C. Practically all of these locations were within an area of four square miles.

The gold area extends twenty-five miles northeasterly from the Salmon River, and is approximately five miles wide. The formation is exposed to Mount Laska, ten miles from Proctor, on Kootenay Lake. The mountain range is easily approached by the narrow valleys of the tributary streams of the Salmon River. There is abundance of timber, and an unusually good water supply, furnishing cheap power for mining and milling. Last winter 20 carloads of ore, coming from different properties and from widely separated veins, averaged over \$100 per ton. On the north side of Sheep Creek oxidized ores are being produced at a depth of over 100 feet. On the south side unaltered sulphides are being mined at a depth of 300 feet below the creek bed, a total difference in altitude of over 2,500 feet.

The sulphides in the quartz consist of iron pyrites, occasionally a little galena and zinc-blende, and, very rarely, copper pyrite. The ores are treated in stamp-mills and concentrating tables.

Associated with the gold in the veins is the mineral wolframite.

During 1908 four properties on the Sheep Creek gold belt produced \$195,000 from a total of 11,600 tons of ore, an average of \$17 per ton.

### NEW STOPE MEASURE.

Mr. O. S. Tonnesen, of the East Rand Proprietary Mines, has invented an instrument for measuring the stopes, which promises to greatly facilitate the work of the surveyor. Mr. Tonnesen calls it the inclined angle method. By means of this instrument and a tape angles and distances are measured directly on the inclined plane of the reef. The instrument is called the "stereometer," and is so constructed that it will measure the true inclined angle between any three points without observing the horizontal and vertical angles, no reductions or calculations being required. It can be held in the hand when observing, and no cumbersome and difficult setting up is required. It may be used for graphical records or be read by a vernier. As this question of stope measurements has been one causing continual dissatisfaction between the miners and surveyors such an instrument will prevent much friction. This was the main cause of the late strike.

The Book Departments of the McGraw Publishing Company and the Hill Publishing Company have been consolidated under the corporate name of the McGraw-Hill Book Company. This is announced to be a consolidation for the making and selling of better technical books. The new concern will have larger and better printing, distributing, and selling facilities than heretofore.

## EUROPEAN COAL MINES.

Address Delivered Before the Coal Mining Institute of America, at Punxsutawney, Pennsylvania.

By J. W. Paul, Mining Engineer, Technologic Branch, United States Geological Survey, in charge of Mine Lighting Investigations and Rescue Work.

The subject, European Coal Mines, is one upon which many volumes have been written, many official reports made, and has been the occasion upon which Royal Commissions have made many inquiries.

Schools, universities, mining institutes, technical societies, testing stations, indemnifying and protective associations in Europe are a few of the institutions resulting directly from the coal industry.

It goes without saying that European mines are much older than mines in our country, and their exploitation has been made largely by native labour, representative of the integral society which furnishes the foundation for their laws and governmental policies with respect to protective measures for all classes of labour, especially mining.

It is not my purpose on this occasion to go into an elaboration covering all the important aspects of the mines in Europe. To do so would necessarily make this paper a lengthy one, and, I fear, somewhat tiresome. Again, the writer has some timidity in endeavoring to enter into a discussion of some important conditions affecting mine safety which have been matters of experimentation and discussion in Europe for the past thirty years.

The first duty of a government is to protect its citizens against all enemies which may cause injury by disease, accident, impairment of health or by attack of foreign foes.

All forms of protective measures entail a pecuniary tax upon the citizens of the government, whether the protection be for naval or military work, prevention of disease or accidents.

In the coal-producing countries of Europe special importance has been given to the adoption of measures which have for their purpose the minimizing of accidents of all classes within mines.

These protective measures are the result of many years' study of the conditions under which different classes of accidents occur and the adoption of practical methods for their prevention.

In most cases the adoption of precautionary methods has added to the cost of the production of coal, but by doing so additional people find employment and the accident list is materially reduced.

The question of discipline within the mines of Europe is frequently mentioned as one of the factors of safety which we have in far less degree in this country. In a large measure the discipline in European mines has been the outcome of many years of training the miners to recognize dangerous conditions.

This discipline does not approach the perfection obtained in the military organizations, but it is obtained in the same manner as in a military organization, by having a sufficient number of experienced and trained mine captains, foremen and bosses to frequently see each man while at his work and direct him as to the proper safety precautions to be observed should any dangerous conditions arise.

Such supervision of the mine work necessarily involves additional cost on each ton of coal which the

people and the industries of the country seem willing to pay.

In matters of statutory requirements and state or governmental inspection, the European laws are largely in the hands of government officials, who have authority to interpret the laws and promulgate regulations relative to their proper enforcement.

The inspectors, in general, have much authority in preventing dangerous practices, and in some countries they may use their discretion in preventing the use of all types of explosives within mines.

With reference to the installation of mine plants, the equipment and buildings as a rule are quite elaborate and constructed along lines of permanency, being mostly of fireproof material, a building practice quite in harmony with the regulations requiring all classes of buildings to be made of incombustible material.

Mine fires in European mines have in the past been the cause of loss of life, and in England and Germany they have resulted in the taking of many lives. Notably in Germany, at much expense, elaborate fire fighting facilities are provided, resembling in every particular a well-appointed fire brigade station, such as is maintained by some of our cities, having fire engines, horses and a crew of trained men.

For underground work of rescuing miners and combating fires, many stations are equipped with different types of rescue apparatus and men trained in their use.

In Austria a law requires that each mine shall be equipped with rescue apparatus, and at all times a certain percentage of the underground employees shall be trained in the proper use of the apparatus.

In France, a similar law is going into effect, and in Belgium, after July 1st next, the collieries will be required to be equipped with the apparatus.

In Germany, many rescue apparatus are kept at the mines, and at central stations where men are trained in the use of the apparatus.

In England, Scotland and Wales, mine rescue stations are established, and miners are being regularly trained.

Rescue apparatus in Europe appear to have passed the experimental stage, since in three of the important mining countries their use is required by law.

In Europe there has been much saving of life through the benefits derived from the several explosive-testing stations, where experiments have been conducted upon mine gases, coal dust and explosives.

In the countries of Great Britain, Belgium, Germany, France, Austria and Russia the Mine Inspector Departments, the operators, and manufacturers of explosives have for their guidance the results of tests made at their explosive-testing stations, and operators of mines are restricted to the use of certain types of explosives, while in Belgium and Austria certain classes of mines are prohibited from using explosives for any purpose within the mine.

As early as 1883 a station was constructed at Zwickau, Saxony, for the study of the effect of explosives when discharged in the presence of explosive gas

and coal dust. Since this was inaugurated the other stations in the different parts of Europe have been installed, and in Bohemia a station is installed underground, utilizing an entry in a tunnel which was excavated about the year 1800.

None of the foreign experimenters have as yet arrived at an acceptable explanation of the phenomenon of a coal dust explosion, although at all of the foreign stations coal dust explosions are produced without the admixture of explosive gas.

In those mines in Europe in which explosives are used for blasting the coal or rock, much attention is given to the condition of the part of the mine where a shot is to be fired with respect to the presence of coal dust and its conditions as to moisture.

Watering of the workings of the mines is practised systematically, being applied by specially constructed cars, by hose and nozzle and by spraying devices.

Much faith appears to be entertained in the wetting of the sides and floor at and within a certain minimum radius of the point at which an explosive is to be fired.

Experiments are in progress in England and Austria to determine the retarding of an explosion by the introduction in different parts of a mine of wet zones, inert zones, and dustless zones.

European countries are fully alive in a concerted endeavor to ascertain what additional safeguards may further curtail the loss of life and personal injury within mines.

Not being fully satisfied with the results already obtained, new and more elaborate testing stations are in contemplation in at least three of the European countries.

The safety lamps in use in the European mines and the manner of handling them are worthy of comment.

In England the lamps are carefully inspected before being taken into the pits, and upon reaching the bottom of the pit a mine official makes a careful inspection of the lamp to see that it is in good condition. It is forbidden to set a safety lamp on its bottom in any part of the mine. When a workman wishes to place his lamp to one side, he must hang it in a safe position.

In Belgium the lamps are looked over by an official on the outside of the mine to see that all of its parts are properly assembled, no test being made of the lamp to determine if it is defective.

In Germany the lamps are cleaned and locked and handed to the miners, who examine them to ascertain if they are in condition suitable for use. In Germany all lamps are without bonnets, to enable the miner to observe the condition of the gauze.

In Continental Europe at many of the gaseous mines each workman is his own fire boss or gas tester—that is, he tests his working place for the presence of explosive gas, and, if found, reports to the proper official. In this particular much reliance is placed in the competency of each of the underground men.

A station of much interest is to be seen within the Nordbahn mine at Maehrisch-Austrau, where a retreat-chamber is provided capable of accommodating three hundred men. This station is about a mile from the bottom of the shaft, and is so arranged that it may be closed with heavy doors and isolated from the atmosphere of the mine. Food, water, ventilation, light, telephones, rescue apparatus and medicines are provided.

In case of a mine fire or an explosion in any part of the mine which might prevent the escape of any living

miner, they may retire to this station and remain until rescued.

With the rescue apparatus in the underground station the men may do much effective work in combating the fire or recovering miners who may be in irrespirable air and unable without assistance to reach the retreating-gallery. This station is another evidence of the aggressive efforts being made to further reduce loss of life in Europe.

Of recent months it is not uncommon to learn of American mining officials traveling Europe making a study of the conditions pertaining to the safeguarding of life, so that it appears that we are beginning to realize that some of the practices in Europe may, with much profit, be adopted in the operation of our own mines.

### POWER AT COBALT.

(Specially Contributed.)

An interesting phase of the situation in Cobalt at the present time is the question of power, and several companies have been formed to supply air and electricity on a large scale to the mines of the district. It is believed that this will mean a great saving, as the present price of steam-generated power is very high. This is due largely to the high price of coal, which averages about \$5.50 per ton on the cars at Cobalt.

It is difficult to obtain reliable figures on the cost of power in the camp, but it is estimated that it will run from \$135 to \$175 per horsepower per year, while the general average will probably be above the \$125 mark. The advent of the power companies into the camp is being followed with close interest, as the rates they offer will probably cut present costs about in half.

A company that is attracting a good deal of attention at the present time is The Mines Power, Limited, who are installing a plant situated on the Matabiche-wan River close to Lake Temiskaming. The requirements of this corporation have been financed by Montreal capitalists, and the head office of the company is in that place. The capital is \$3,000,000, and as the money has been advanced by the promoters, there is no stock or bonds on the market for sale. The president is Mr. E. A. Wallberg and Mr. F. J. Bell is the general manager.

The powerhouse will be situated on the river already mentioned, about twenty-five miles from Cobalt, while the company have also obtained the right from the Government to dam up the waters of the lakes above the falls, as they see fit, to supply sufficient storage capacity in case the water in the river should fail. The dam above the powerhouse is being built of solid concrete, and will have a length of eight hundred feet and a height of forty-five feet. There will be two five-foot penstocks, while the working head will be 312 feet. It is estimated that a total of 15,000 horsepower can be generated.

The powerhouse will be a solid concrete building, forty by ninety feet, and will be fitted with travelling cranes. At present there are four separate generating units being installed. Each generator is rated at 1,875 kw., with a large overload capacity, and provision is being made for extensions to the powerhouse equipment. The units that are now being installed will supply the present requirements of the district. The generators are three-phase, sixty-cycle, 2,300 volts. The wheels are spiral case turbines, with a capacity of 2,750

horsepower each. These will be directly connected with the generators. There will be two exciter units, each with a capacity of 100 kw., and each exciter will be directly connected to a water wheel. To insure perfect regulation, high power governors are being installed. The step-up transformers are also of the three-phase type, and there will be four in the continuous service, with an extra as spare in case of accident. These transformers will increase the pressure to 44,000 volts. Two separate three-phase transmission lines are being constructed, each having a separate circuit. Aluminum is being used for the conductors, and these will be supported by high-tension porcelain insulators.

The right of way is being cut one hundred feet wide through the woods, and also all high trees on either side in close proximity, so that the wires may not suffer. For the delivery of the power three substations will be built. One will be in South Lorrain, with a capacity of 1,000 horsepower; one at Kerr Lake, with a capacity of 2,500 horsepower, while the remaining capacity of the plant will be at the other station at Cobalt. These stations will consist of three-phase step-down transformers, with the usual lightning arrester and switchboard equipments. The distributing system from the different substations will be three-phase sixty-

cycle 2,200 volts. At the Kerr Lake and Cobalt stations there will be electrically driven compressor plants, with spare units. At Cobalt the plant will consist of three direct-connected motor-driven three-stage compressors, each having a capacity of 4,200 feet of free air per minute. The plant will have extra large intercoolers and aftercoolers. The air will be delivered at 100 pounds, and atmospheric temperature through radiating pipe lines from the central station to the surrounding mines, and will be sold to the consumer on a meter basis.

On the upper lakes, dams are now being built, while on the powerhouse and the concrete dam there is a force of four hundred men employed. On the right of way three separate gangs are employed. The whole plant consists of practically duplicate units, and every precaution is being taken by the company to insure continuous service. It is expected that power will be ready for delivery by September 30th.

This company also intend to extend their transmission lines to Elk Lake and Gowganda. They also control the Kakake waterpower on the River Quinze, which power is being held in reserve for development as the market extends. This power alone has a capacity of about 40,000 horsepower.

## METALLOGENETIC EPOCHS.

By Waldemar Lindgren, Washington, D.C.

Paper Read Before the Canadian Mining Institute, Annual Meeting, Montreal, March, 1909.

The difficulties of a student of mineral deposits are increasing. As in petrography the first descriptive period of the science is drawing to a close. We know the principal types, and, though much remains to be done in detailed accounts, it seems that we are gradually coming to the same "impasse" which confronts the petrologist, who is now turning to the exact experiments of physical chemistry for the solution of the riddles which confront him. And as we transfer some of our most important problems into the same able hands for experimental work at high temperatures and pressures, some of us may confess to a slight feeling of disappointment that inductive work has failed to furnish definite answers to many of our questions. But such a state of mind should only be like the shadow of a passing cloud; for the study of mineral deposits is not a science distinct from others; it leans on all branches of geology as well as on chemistry and physics, and this new development means not only that we have taken a step in advance; that we have acquired a new and powerful collaborator; it means also still further specialization. It does not mean that the scientific services of the mining geologist will be unnecessary or futile. His work will be necessary to assemble and assort the facts, to test the results of the laboratory, to propound new problems, and to generalize from the study of wide areas.

This critical examination of mineral deposits over wide areas is a work which now confronts us. It is the geographic and historical side of our science. With some hesitation I venture to place before this Institute an epitome of the principal epochs of the segregation of metals over our continent. Many of the facts are well known to you and the only feature of this paper

which can possibly merit your attention is the summarizing of these well known facts.

This continent of North America is rich in metallic wealth; its total production exceeds that of any other equivalent division of the earth. Gold and silver come from the Cordilleran belt and also from the eastern margin of the continent. Copper in ever increasing quantities is derived from the Central Basin and from deposits in the west extending from Sonora to British Columbia. Lead and zinc are produced from our vast Mississippi basin and from the ranges of the Rocky Mountains. Half of the world's nickel is drawn from Ontario and a large part of the tungsten comes from Colorado. The total value of the metallic product of the continent in 1908 was about \$1,000,000,000.

In some measure we have succeeded in classifying the vast number of deposits, not only with reference to their mineralogical and structural characteristics, but also with reference to their age. We find that metaliferous deposits have been formed since the earliest times of geological history. We find also that they are not equally distributed over the continent, but occur in metallogenetic provinces of greatly different form and extent. Moreover, these metallic concentrations have not been going on at equal rates throughout geological time, but the formation of each group corresponds to fairly brief epoch which, with few exceptions, is also a epoch of vulcanism. No fact is better established than this, however much we may differ in details of genetic history. On the other hand, regions of vulcanism do not necessarily contain ore deposits. Naturally we find the ores in regions of uplift and erosion, for here the rocks are best exposed, but they are not necessarily connected with such warpings and corrugations, as is

illustrated by the oft-cited poverty in metalliferous deposits of the Appalachian ranges of sedimentary rocks.

Since the earliest times, then, metallogenetic epochs have recurred on the North American continent, and, comparing it with others, we must conclude that either the original sources from which the ores have been concentrated have been richer than elsewhere or the conditions for their formation have been more favourable than elsewhere.

### Metallogenetic Epochs.

In describing these epochs it will be convenient to separate the eastern and the western halves of the continent for, with exception of the earliest part of their history, they have little in common.

### Epochs of Ore Deposition in the Eastern Part of the Continent.

1. The Pre-Cambrian Period.—The Pre-Cambrian period embraces a very long time and many different epochs of ore formation; but for our present purposes it will be necessary to consider it as a whole. Ages of sedimentation alternated with violent igneous action. At many places long erosion preceded the deposition of the Cambrian. The Pre-Cambrian deposits form a belt along the southern Appalachians, extending northward into Canada, where they are found over a wide area. They occupy parts of Michigan, Wisconsin, and Minnesota, and re-appear in the west, in South Dakota, Wyoming, Colorado, New Mexico and Arizona; possibly also in south-western California, but with less of the diversity characterizing the Lake Superior region. In the latter region there is a great succession of igneous rocks, effusive as well as intrusive, ranging from granites to basalts, diabases and gabbros. In the Corbilleran region the intrusives are almost exclusively represented and the prevailing type is the normal red granite contrasting strangely with the later intermediate type of intrusives. Smaller amounts of intrusive diorite, gabbro and diabase are present.

The metals characteristic of this period are iron, copper, nickel, gold and silver. Lead and zinc appear to be present in far smaller quantities than in later periods. Quicksilver and antimony are rare. The iron ores are, as well known, of several types; the ilmenites and the magnetites are chiefly of igneous origin; the hematites of Lake Superior, according to Leith, of partly igneous, partly sedimentary origin, and ultimately oxidized and concentrated by surface waters. It is believed that this concentration took place mainly in Pre-Cambrian time. The copper and nickel ores are connected with basic igneous rocks, in part intrusive, in part, as in the Michigan copper region, of effusive type. The concentration of the copper of this latter region into workable deposits also seems to have taken place chiefly, if not wholly, in Pre-Cambrian time, and probably followed the close of the igneous activity in Keweenaw time. The silver veins of Cobalt, which have proved so rich, are likewise Pre-Cambrian and some writers are inclined to connect them with Keweenaw basic intrusives into Huronian rocks.

In the Southern States the deposition of the gold-bearing quartz veins in most cases directly followed granitic intrusions in various sedimentary schists. The assertions of earlier writers, that these veins are generally connected with basic intrusives, are not supported by recent work. Some silver and copper are associated with these gold-bearing veins. It should be

added that some writers assign a Cambrian or even later age to the southern granites. Minor copper deposits in the same region are chiefly derived from intrusions of diabase or allied rocks. Pre-Cambrian gold-quartz veins are also known from Western Ontario.

2. Epoch of Paleozoic Intrusives.—From New York and New England northward into Quebec and Nova Scotia granitic intrusions took place at various times during the Paleozoic as late as the carboniferous and were accompanied by some metallization. The gold-quartz veins of Quebec and Nova Scotia were in part, at least, formed after these intrusions and various small deposits in New England have a similar origin.

3. Epochs of the Sedimentary Iron Ores.—Processes of sedimentation under favourable conditions lead to concentration of iron ores. During the long period of unbroken Paleozoic sedimentation in the Appalachian region there were at least two epochs which are characterized by such iron ores. During the Clinton stage of the Silurian, persistent beds of low grade hematite were formed; and during the Carboniferous less important layers of carbonate black band ores were deposited.

4. Epochs of the Triassic Traps.—The important period of the history of the igneo-genetic ore deposits of the eastern part of the continent closed in the late Paleozoic and the majority of these deposits had been formed much earlier. A feeble recurrence of ore formation took place during the early Mesozoic, when the traps of the Eastern States were injected as sheets or overflowed as lava streams. Smaller masses of iron and copper ores developed along the igneous contacts, in part as veins, in part as contact meta-morphic deposits.

5. Cretaceous, Tertiary, or Later Epochs of Zinc and Lead Concentration.—Since the Triassic, vulcanism has rested and in the eastern part of the continent metal deposits have formed only by the concentrating power of flowing surface waters or of ground-water in decaying rocks, or of ascending waters of atmospheric origin.

In the central valleys, such ore concentration has been effected in comparatively late time, apparently independent of vulcanism, and has resulted in the most important lead and zinc deposits on the continent. Regarding the mode of origin of these deposits opinions differ widely, but most observers believe that the lead and zinc has been leached by surface waters from Paleozoic limestones which derived their sparsely disseminated content from the Pre-Cambrian northern continent. Some regard the process as a simple affair of downward percolating surface waters. Others attribute it to vigorous ascending circulation of atmospheric origin. The time of this concentration is thought to range from the establishment of a circulation dependent upon uplift, perhaps from the Cretaceous to the present time; but some geologists have not hesitated to say that ore concentration began in late Paleozoic or in Mesozoic time. Further discussion cannot be attempted here, but with reference to the theories just indicated it may be worth while to point out that lead and zinc deposits are very scarce in Pre-Cambrian rocks and the latter would hardly seem to be an adequate primary supply. There is undoubtedly much evidence in favor of concentration by ordinary surface waters, but the lead-zinc deposits in Kentucky and Arkansas certainly show transition into types, which closely resemble western types of veins, attributed to hot waters. The ores in the more important districts appear to convey the impression of sharply defined

depositional epochs, rather than of long continued action of cold waters descending from the surface.

### Epochs of Ore Deposition in the Western Part of the Continent.

The metallogenetic history of the Cordilleran region is more complex than that of the eastern half of the continent, but it is in some respects easier to interpret.

1. The Pre-Cambrian Period.—The Pre-Cambrian Period, as already mentioned, was productive of gold and copper deposits scattered from South Dakota through Wyoming, Colorado, New Mexico, and Arizona. South and west of this area the Pre-Cambrian is lacking; north of it, these old formations are present in places, but appear to contain no ore deposits formed during that period. In the Black Hills of South Dakota and in New Mexico some deposits referred to this group have been clearly shown to antedate the Paleozoic, and others in Arizona give strong inferential evidence of as great geologic age.

The Pre-Paleozoic gold deposits are generally lenticular quartz veins in schists, associated with heavy gangue minerals like tourmaline, garnet, etc. The copper deposits which usually contain chalcopyrite, are veins or irregular masses, the latter often of magmatic origin, but modified by dynamo metamorphism. Zinc blende is sometimes found with the chalcopyrite. Lead is almost wholly absent.

Throughout the Paleozoic, and the larger part of the Mesozoic the great interior province, now occupied by the Rocky Mountains, was the scene of almost uninterrupted sedimentation. Land areas existed here and there, but the igneous forces, so active over the whole country in pre-Cambrian time, were quiet for ages.

Not so along the Pacific coast; for here we find in places evidence of intrusions and lava flows dating back to the early Paleozoic. As yet it has not been shown that mineral deposits of that date exist along the coast.

2. The Early Mesozoic Epoch.—Between the Carboniferous and the Triassic, uplifts and folds had raised the Paleozoic sediments and the early Mesozoic beds were deposited uncomformably on the older rocks. Some time during the Triassic an epoch of intense igneous activity began and continued through the Jurassic. Basic lavas, mainly of the types of diabases and andesites, were erupted, largely as volcanic flows, from California to Alaska. A distinct epoch of metallization, principally yielding copper deposits, accompanied or followed these eruptions. We shall not err greatly in ascribing some copper deposits of California, British Columbia, and the Copper River region in Alaska to this, the second metallogenetic epoch definitely recognized on the Pacific coast.

3. The Late Mesozoic Epoch.—The third and most important epoch followed the intrusions of the great batholiths of the Pacific coast to which an early Cretaceous age is generally assigned. These intrusions of intermediate quartz-monzonitic or granodioritic character took place upon a scale difficult to grasp in its immensity. The present exposures show two main granitic masses, possibly connected beneath the Tertiary lavas. The southern batholith extends through California, the northern batholith stretches from Washington up through British Columbia to Alaska. Another smaller mass now occupies the central part of Idaho. Innumerable intrusives of less volume broke through the crust in Southern California, Southern Arizona, Western Nevada, Oregon, and elsewhere. The age of

the batholith of Western Montana is somewhat in doubt, it may belong to a later epoch. But throughout this revolution and the birth of the mountain ranges on the coast, the Cretaceous was being quietly deposited at sea level all over the eastern Cordilleran region.

An epoch of intense metallization followed these intrusions, within the areas indicated. The great interior masses of the batholiths are usually free from deposits, as shown in the High Sierra, in the Clearwater region, and in British Columbia. But along their margins mineral deposits formed in abundance, as along the gold belt of California, and along the two contacts of the batholith of the Canadian and Alaskan coast regions. The latest researches by the Alaskan division of the United States Geological Survey indicate that the great placer fields of Alaska derived their gold from deposits of this epoch. Gold, primarily, and copper, secondarily, are the characteristic metals. Along the Pacific coast, where there is little limestone in the intruded sediments, lead is practically absent, but in the interior, as in Nevada and Idaho, where the intrusions came into contact with Paleozoic limestone, this metal, with zinc, begins to appear. Silver is everywhere present, but scarcely ever important, except where lead appears. Arsenic and antimony are not abundant, mercury is nowhere present in commercial quantities.

4. The Early Tertiary Epoch.—As if exhausted, the igneous forces appear to have rested until the close of the Cretaceous and then broke out in a new field, along the eastern margin of the Cordilleran region, at that time largely covered by a plastic mantle of Cretaceous shales and sandstones, several thousand feet in thickness, which rested on great accumulations of Paleozoic limestones.

The predominating magmas were again of intermediate character, and solidified as granular or porphyritic rocks, standing between the granites and the diorites; they contrast markedly with the potassic and acidic magmas of pre-Cambrian times. While it is not necessary to limit strictly this igneous activity to a certain time, there is little doubt that most of it took place in the Eocene. The eruptions mainly took the form of intrusions and largely that of laccoliths, undoubtedly because, unlike the conditions of the shattered rocks of the Pacific coast, they were covered by this heavy, tough and still yielding mass of Cretaceous sediments. We find an enormous number of these intrusions as sheets or laccoliths at various horizons between the Cambrian and the Cretaceous or as dikes or stocks that break through the underlying pre-Cambrian. They are rarely comparable in extent to the great batholiths of the coast. They occur from British Columbia, through Montana, Colorado, New Mexico, eastern Arizona, and probably attain their greatest development in eastern Mexico. For reasons already indicated many, perhaps most, of these intrusives never reached the surface. Only in a few cases, as in Montana and in Colorado, near Denver, do the strata of Laramie or Eocene age contain volcanic detritus.

The third Cordilleran epoch of metallization followed these intrusions; contact metamorphic deposits and veins were formed in abundance around their margins. The characteristic metals are silver and gold with much lead and zinc, especially where the intrusions cut the limestones. Copper and iron are also present at such limestone contacts. Arsenic and antimony are far more in evidence than during the second epoch, but mercury is still absent.

5. The Late Tertiary Epoch.—Orogenic disturbance

followed the intrusions; the whole Cordilleran region was lifted high above sea level, warped, and faulted. These disturbances may have facilitated sub-aerial eruptions; at any rate it is certain that the middle and close of the Tertiary witnessed outflows of lavas upon a magnificent scale.

These eruptions spread over a large part of the western part of the continent; less pronounced in British Columbia and Alaska, they are abundantly represented in California, Washington, Oregon, Idaho, Colorado, Utah, Nevada, New Mexico, Arizona, and attained their greatest development in Mexico. Andesites and rhyolites are the predominating rocks. In some places the flows attained such thickness that during the later part of the volcanic epoch intrusions of magmas consolidated in them with granular structure.

During these eruptions, not strictly contemporaneous throughout, a fifth metallization took place, of which the characteristic metals are gold and silver. These deposits were often of great richness which is further accentuated by secondary processes; in fact most of the "bonanzas" belong to this class. Lead and zinc are not conspicuous except where the metallization took place in limestone. Copper is not abundant. Tellurium and antimony are common. Not that they are absent in older metallizations, but they, especially tellurium, seem particularly characteristic of this epoch.

Large areas of volcanic rocks are barren. The metal deposits seem to have formed only near or at the foci of igneous activity, where connection could be established with underlying magmas. The most recent eruptions were mainly basalts, and these, except in one case, do not seem to have been affected by metallization.

6. The Post-Pliocene Epoch.—The youngest metallogenetic province is that of the Pacific coast line. It is of very late age—Post-Pliocene apparently, and is characterized by mercury accompanied by few other metals. It developed in the coast ranges of California, following basalt eruptions and contemporaneous with it was a great development of hot springs. In part the deposition goes on at the present time.

Note that the quicksilver did not develop simultaneously with the birth of the coast ranges; these are much older, and an active circulation of atmospheric water was undoubtedly established long before the quicksilver deposit was formed.

7. Cretaceous or Later Epochs of Copper Concentration in Sedimentary Rocks.—In addition to these six classes, whose connections with igneous rocks are indubitable, the disseminated copper ores of the south-west should find mention. They occur in sandstones, shales, or conglomerates ranging from the Carboniferous to the Cretaceous, and, in most cases, chalcocite is the primary ore; frequently small amounts of silver are present. New Mexico, Arizona, Utah, Colorado, and Texas offer numerous examples of this class. While their origin is not wholly clear, many observers believe that they represent concentration by groundwaters of small amounts of copper originally derived from the pre-Cambrian deposits and since distributed through late sedimentary beds.

Summing up, we have then in the Cordilleran region:—

|                                                            | Principal metals.                                 | Principal rocks associated with deposits.     |
|------------------------------------------------------------|---------------------------------------------------|-----------------------------------------------|
| 1. Deposits of Pre-Cambrian period.                        | Gold and copper. . . . .                          | Granites<br>Diorites, gabbro                  |
| 2. Deposits of early Mesozoic epoch .                      | Copper . . . . .                                  | Basalt, diabase<br>Gabbro                     |
| 3. Deposits of late Mesozoic epoch .                       | Gold . . . . .                                    | Granodiorite<br>Quartz-monzonite              |
| 4. Deposits of early Tertiary epoch..                      | Gold, silver. . .<br>Copper, lead, zinc . . . . . | Granodiorite<br>Quartz-monzonite<br>Monzonite |
| 5. Deposits of late Tertiary epoch..                       | Gold, silver. . .                                 | Andesite<br>Rhyolite                          |
| 6. Deposits of Post-Pliocene epoch . .                     | Quicksilver . . .                                 | Basalt                                        |
| 7. Cretaceous or later concentrations in sedimentary rocks | Copper . . . . .                                  | Sandstone, shale<br>Conglomerate              |

As the surface of the earth is brought near to any deposit by the erosion of covering rocks, the chemical action of descending oxygenated groundwater, finally also the transplanting activity of running waters, are brought into play. Enrichment by simple oxidation or by the formation of secondary sulphides may then take place. Migration of metals into adjoining rocks may also follow. The heavy indestructible minerals will be sorted out and accumulate in the gravels of adjoining streams. In short, each primary deposit may be the parent of several of secondary grade, and the later are usually the richer. But the secondary deposits cannot be classified on the same basis as the primary, for groundwater and surface streams may at the same time attack deposits of widely differing age, and, under favourable conditions, such secondary migrations may be in progress at a given primary deposit for long periods of geological time.

Several observers have noted that the character of metallization appears to vary with geological time. In the above summary, this is illustrated by the almost exclusive appearance of important quicksilver deposits in recent epochs. Others have laid emphasis on the varying depth below the surface at which the deposition took place, maintaining, for instance, that, because certain sulpho-salts of quicksilver are easily soluble, they would remain in solution in the ascending waters until the surface had nearly been reached. Neither view, probably, contains the whole truth. It is evident, for example, that many deposits of gold, silver, and other metals have been formed near the surface in volcanic regions, in which quicksilver is wholly absent.

In deposits that are clearly connected with igneous rocks metallization is certainly a function of varying pressure and temperature; these factors being dependant upon depths below the surface and other conditions; metallization is also dependent on the nature of the rocks in which deposition takes place. Primarily, however, it is probably a consequence of magmatic differentiation.

It is well established that magmas of different types contain different associations of the rarer metals. For instance, tin and tungsten characterize acidic rocks, while nickel and cobalt are found chiefly in magmas rich in ferro-magnesian constituents. At the same time rocks of a given general composition may, in different

localities, vary considerably in the quantity of rarer metals contained.
